From: jo barden
Topic: 20989 Message: 21030

PEP, this is a good explanation http://vk1od.net/measurement/RfPowerTerms/PEP.htm effectively it is the same as DC in that it deals with RMS values and RMS is the same heating effect as DC.

I would however point out that intensive modes such as RTTY require that the output power be reduced otherwise overheating etc. can occur.

As for Baluns I have made my own, tried them out on the air and dismantled those that were not any good. I have used "cheepo" no name toroids and in all honesty they were utter rubbish. I ended up with all sorts of readings so my advice is to buy named toroids.

Have fun, make antennas and get on the air.

Topic: 21031 Message: 21031

What is the easiest and safest way of bringing 450 Ladderline into the shack? Can one use two bulkheads for this? I wanted to install those 4" standoff insulators but cannot find them.

Too many ways to skin that cat ... :-)

Brass rods trough wooden block? Or 2 holes in insulating plate in the window
Or do you have a break trough panel in your window (to mount the standoffs
on)???

2 wires trough 2 holes in window frame (only if it is YOUR window)

Some use 2 lengths of coax ... (shield is grounded)

Some use only the inner part of coax (no shield)

You can easy make your own insulators from scrap ... so look in your junkbox
hi hi

We would need some details to help you here ...

Any other wires to bring in the shack???

Should the panel (in the window) made from metal and grounded ??

The easiest way is to use a window bulkhead like the MFJ-4600

http://www.mfjenterprises.com/Product.php?productid=MFJ-4600

The next easiest is to look at the picture and description and build one.
If you can find a scrap of a Formica counter top, that would provide you
the basic material. A few threaded rods with washers and nuts, some
weather stripping, and you're in business.

Topic: 20989 Message: 21034

Well I am always happy to answer you, just don't ask me what the mix of the rods are. I got some nice 1/2 inch diameter rods 8 inches long from a friend who got them at a hamfest, they were NOS, packaged well but not marked for mix. I also got some very cheap 10mm dia x 200mm long from a ham in Lithuania, he sell Russian surplus on E-Bay. Rods are cheap but shipping is high. I was making a filament choke for a 4-1000 amp at the time, work great for that also.

You could always try old loopsticks.

Rich, Kd0zz

Subject: Re: [ham-antennas] 4:1 Balun winding questions please?

Great idea. Can you get rods cheaper than the toroids?? And will old AM radio loopsticks work okay?

Subject: RE: [ham-antennas] 4:1 Balun winding questions please?

Some wrap the core or rods because they need more insulation between the wire and core. I only wrap bare rods. You won't need it because of the heavy
insulation provided by the Teflon. Some magnet wire that is designed for motor use has a thin coat, other magnet wire has a much thicker coat.

The number of turns will depend on the wire insulation and core type. When you complete you winding you can do it with , let's say one more winding, then check the resonate frequency of you balun. It would be easier to remove a winding than add one.

A note about winding with Teflon wire, it is a little harder to hold in place than magnet wire. It will spring back or unwind. I use little spring clamps or paper clamps and hold the wire in place, apply some quick set epoxy. When doing a 4:1 current balun a torrid I use little alligator clips
I got at Harbor Freight to hold the spacing until the epoxy dries. On a rod
type I use monofilament fishing line to hold the spacing.

Rich, Kd0zz

Subject: [ham-antennas] 4:1 Balun winding questions please?

I'm going to wind my first 4:1 balun and no matter how much I read I cant find the same answer twice so why not ask. I'm using a T200B-2 core and silver plated Teflon covered wire #16. First question, why do some of the how to's want you to wrap the toroid core in tape and other don't?, secondly, even though all are saying they produce a 4:1 for HF why do the number of turns vary so much? Lastly, when they say 14 or 16 turns I'm assuming they mean "total" turns, both sets of windings, IE (8 on one side
8
on the other)?

Sigi,
you gave me some idea's! Window made of aluminum so perhaps I cut a 2"X4" and I can cut out a 2" slot as thin as the ladderline is and slide it through thus giving it a bit of resistance to hold it in place in the 2X4. This would work best. Now the search is on for a tool that can cut that slot. The 2X4 will lay underneath the window itself.

Well if you are using a balun, I would say that the easiest way is to put the balun outside the window and run a short length of coax to the rig.

If you use a board, you should have insulators, especially if you are running high power. If the window has a metal frame, you could arc over to it if you just run the open wire up against the frame.

Right now I'm just closing the vinyl (double hung) window on twin lead but I plan to move the balun outside in the next few days.

OK , now that you have 101 ways to run ladder line in thru your window and you make the board/panel for the feed-thru and close the window on it you will find the top of the window section that you moved is no longer sealed,from the cold air and the ends of your feed thru..Cut a filler strip of wood or plastic and go to your local hardware/home depot, Lowes and buy a tube of Dap brand caulk called -Seal 'n Peel- it is a clear removable caulk for weather stripping. You can put it on this year and if you want to change next week or next year it is easy to remove. It will pull off sort of like a rubber cement.

Rich, Kd0zz

ever and get a tube of,___

PEP is four times the no-audio carrier power in with symmetrically modulated AM, Larry.

Figure it this way, your 4kV w/ no modulation will rise to 8kV on positive going audio peaks... remember "peak(s)".
The current will also double... I=E/R.
So twice the voltage times twice the current will net out to four times the DC input power - four times the RF power.

The typical solid state SSB/AM rig rated for 150 W. PEP should be set up to deliver one quarter of 150... or 37.5 W. (if I did my math right) when in AM service. Doesn't really sound like all that much, do it? ;-)

. And just reading the sales pitch doesn't help at all. They all say legal
limit, and DC to daylight! From what I’ve read thus far, that is mostly
under “ideal” circumstances and not the real world, kind of like antenna
gain specified against isotropic

Jim that DC to Daylight is what got me into doing my own baluns. I tried
one of the older ham call sign named, store bought balun that covered
everything from 160 and up. Well not too good on a solid state radio, might
have been ok on a older tube radio like my Johnson rig. I built a voltage
4:1 balun , it was easy and it worked. I then built a current one on a
torrid, next on twin torrids with a acrylic spacer and at last twin rod type
for the widest range of good SWR readings. I now use it on a multiband loop
antenna as my main antenna set up.

> killoWatt.

Don't complain, that was only 700 or 800 Watts OUT. Our current limit is 1,500 Watts OUT. Just about double what it was.

<<
Peak Envelope Power means the average power supplied to the antenna transmission line by a transmitter during one radio frequency cycle at the crest of the modulation envelope taken under
normal operating conditions.
>>
from : http://vk1od.net/measurement/RfPowerTerms/PEP.htm

PEP for CW is 1,500 Watts OUT "key down."
PEP for SSB is 1,500 Watts OUT at the crest of the modulation envelope
PEP for Am is 1,500 Watts OUT at the crest of the modulation envelope without modulation that is
about 350 Watts of unmodulated carrier. We took a hit there, but since it is a minor used mode
that's OK. We gained elsewhere.

BTW: According to our current rules you can legally operate with the old rules, that is with 1,000
Watts input.

Another thought on bringing in ladder line, LIGHTNING. The suggestion to use a balun and bringing in co-ax will allow you to ground the shield just outside of the dwelling, giving a strike a good path to ground. You DO NOT EVER want to invite the big bang into your house... he's a lousy dinner guest!

Buddy of mine down in Melbourne, FL (center of the lightning capital of the world) with a 100' tower right next to the house took three hits in 5 years. twice it blew holes the size of your fist in the walls of more than one room and he had to have his house completely rewired..After the 3rd strike the insurance companies refused to insure him for lightning related damage anymore :-) . After the 2nd strike his XYL refused to be in the house during a thunder storm and went to a motel with the kids ...after the 3rd strike she divorced him :-)

Ladder line is no more or less susceptible to damage from L-strikes than coax when it comes to a direct hits

I use a circular saw to plunge (start) a blind cut in sheet material
for a slot, just be careful have far you plunge in the blade.
Also a table saw with a small diameter saw blade makes the
same plunge cut, usually a LOT neater, and much more controllable
for depth/slot length.

Roto-Zip might have trouble cutting all the way through a 2 by 4. One option would be to drill a hole through the wood, use a jig saw to cut the slot starting at the hole, and then fill the hole with a dowel. The blade of the jig saw would make a cut just about the right width.

Lightning is the proverbial 500# canary....it will go anywhere it darn well pleases.

Coax has the advantage of having a good ground (hopefully) within a quarter of an inch. Not that it really matters with a direct strike.

Hmmm... It would be very interesting to see what Mr. Florida ham had in place to keep his home safe from lightning.

The pros do it all the time; TV and radio stay on the air during the severe lightning storm as do the cell phones and the sheriff's radio system, while the typical ham may not even be aware of what he needs to do.

I've been involved in correcting what otherwise looked like a very nice, very professional looking, commercial installation... 80' tower, 3' leg to leg, etc. A real pro looking job...

BUT, the three ground rods (the only rods) were driven in right next to the concrete base. The cables were not bonded to the tower where they left it to run into the building. The entrance into the building was a joke.

After loosing two radio systems they called us back in (we had warned them several times, but sometimes you got to get hit in the head to listen.)

We added three more rods at the tower, spaced sixteen feet away from the existing. Bonded the cables, added an entrance panel with lightning arrestors (I said the building end was a joke), tied it to several more spaced rods and now it all holds together.

The last call I took from there was to replace a fuse in the PA amp that had failed because the other one in parallel with it (and this from Motorola) failed open leaving its neighbor to handle the whole load.

True, some installations do defy correction... the power comes in on one wall, the telco and cable TV on another and the best run from the antenna farm through another wall. And your shack is on the second floor to boot. A tough situation, but not unfixable. Just costs a lot of dough and some inconvenience while the halo ground and entrance panel are installed.

Buddy of mine down in Melbourne, FL (center of the lightning capital of the world) with a 100' tower right next to the house took three hits in 5 years. twice it blew holes the size of your fist in the walls of more than one room and he had to have his house completely rewired..After the 3rd strike the insurance companies refused to insure him for lightning related damage anymore :-) . After the 2nd strike his XYL refused to be in the house during a thunder storm and went to a motel with the kids

...after the 3rd strike she divorced him :-)

Ladder line is no more or less susceptible to damage from L-strikes than coax when it comes to a direct hits

Stan,

What do you recommend for grounding when there is a layer of bedrock only 3' under the surface?

Actually when I tune my tube amp (SB-200) I use my key. I just don't hold it for a long time. It tunes up real quick that way. I start out with 20 W on the radio then when its tuned I up the output on the radio to 50 W and tweak the tunning. Real easy.

I know nothing about solid state amps. My friend tunes with his tuner first then the amp is just fine. He has a solid state or SS amp.

73, WY6L

PS you can also put your main question in Google and see what you get from there.

Shows what I know. I thought he meant linear loading of an antenna, as opposed to lumped parameter coils. I was going to recommend this link:

http://www.qsl.net/pa3hbb/ll.htm

If he means loading up a linear amplifier, that link won't help much.

Hi Rich...

AFAIK, Rich, the ARRL does not have publishing rights to Sevick's "Transmission Line Transformers". They may have published it at one time, maybe in the 80's, but I can't find a record of it. Latest publishers were listed as SCITECH Publishing and Noble Publishing.

There are a couple of copies listed as "New", but the prices are all over the place... which, to me, means no active publication. That being the case, it'll probably show up as an e-book someplace.

The books published by the ARRL are usually very reasonable in price. If you compare the price, and then look for a comparable technical book for a college level course, you'd be in for a very rude awakening. Last child just out of college... cost of textbooks averaged $1000/semester.

Another place to look for tech books is the publishers of the monthly online antenna magazine... antennex.com. Some are available printed, but most are ebooks available for either download or as a cd rom; I've been happy with my purchases. Topics are mostly antenna related, but they have do carry other tech books. Some are translations from other languages... I'd like to see more of these. Purchased the antenna modeling books by Cebik earlier this year... good material!

.....Just visited there and they are selling an updated version of "The RF Desk Reference", by Harold Kinley, WA4GIB... always something "new".

However, I, like many others, have a problem when it comes to antenna related books.... you just can't have 1, or 2, or 3 or..... !

"linear loading" is an antenna technique used to shorten an antenna element without using loading
coils with the same effect. It looks to simple to believe it works.

PEP is four times the no-audio carrier power in with symmetrically
modulated AM, Larry.

Figure it this way, your 4kV w/ no modulation will rise to 8kV on positive
going audio peaks... remember "peak(s)".
The current will also double... I=E/R.
So twice the voltage times twice the current will net out to four times
the DC input power - four times the RF power.

The typical solid state SSB/AM rig rated for 150 W. PEP should be set up
to deliver one quarter of 150... or 37.5 W. (if I did my math right) when in
AM service. Doesn't really sound like all that much, do it? ;-)

I still have trouble knowing what PEP is. The old DC input was simple.
4000 volts times 250 milliamps equaled 1000 Watts. That was a REAL
killowatt.

Subject: RE: [ham-antennas] 4:1 Balun winding questions please?

. And just reading the sales pitch doesn't help at all. They all say legal
limit, and DC to daylight! From what I’ve read thus far, that is mostly
under “ideal” circumstances and not the real world, kind of like antenna
gain specified against isotropic

Jim that DC to Daylight is what got me into doing my own baluns. I tried
one of the older ham call sign named, store bought balun that covered
everything from 160 and up. Well not too good on a solid state radio,
might
have been ok on a older tube radio like my Johnson rig. I built a voltage

4:1 balun , it was easy and it worked. I then built a current one on a
torrid, next on twin torrids with a acrylic spacer and at last twin rod
type
for the widest range of good SWR readings. I now use it on a multiband
loop
antenna as my main antenna set up.

#1 - the National Electric Code requires either insulators or coax (at least it used to, I assume it still does)

#2 - a bare 2x4 will absorb water and be a poor insulator when it rains. If you are going to ignore #1, at least use some heavily insulated wire (like RG-8 coax center conductor) for going through the 2x4.

Before I saw this I went to Loews Home Improvement and purchased a dremel tool that saws and cut the slot out on the board for the ladderline. I was not very impressed with this tool and it jumps around on the board in the beginning so don't think I will use it for the application you are speaking of Van.

Or run two equal lengths of coax through two holes and calk them in.
Solder the two shields together at both ends and ground them on one end.

I'm in the middle of getting this house ready to sell. One of the last big projects was my office/shack. New floor and patch/paint the walls. That meant the hole through the exterior wall for the coax cables had to go.

Normally I'd probably make something like this but I have no time for ham projects right now and I didn't want to decommission this QTH yet. For $60 and literally 10 minutes of installation time I was back on the air the same night I moved the furniture and equipment back into the room.

Already have a hole through the wall in the new house and the windows there are all casements anyway. I'm sure it'll make it's way to a flea market some time in the future.

If that were my situation, Ken, I'd cut the rods to length and run multiple runs of copper, like radials under a vertical.

The rule of thumb for rod spacing is twice the depth... 16 feet for 8 foot rods, but I'd probably go... say eight feet between the shorter rods, linearly and side to side. Mainly the strike needs to be spread out over the greatest area to allow it to dissipate.

I've seen write-ups for stations sited on mountain tops with nothing but rock for a base. I think they go for capacitive coupling to the earth to do the job. But, the whole station needs to be contained in a kind of electrical bubble. All the services enter the facility through ONE and ONLY one entrance point. That way, the whole site jumps to a potential but the contained equipment feels nothing. Having multiple unbonded entrance points allows differential current to flow though the equipment (or the house) with painful results.

Stan,

What do you recommend for grounding when there is a layer of bedrock only 3' under the surface?

Those would work fine, but if you have Lucite/plexiglas for the window, you can go right through it without an insulator. Plexiglas is a good insulator itself, of course.

Actually, our basement windows had plexiglas in them when we bought the house and I just drilled holes through that.

I just purchased a copy of Sevicks
'Transmission Line Transformers'
from Amazon.com and a bookstore they carry.
It was the ARRL version, LEATHER-bound, used condition-Good,
for $1.23 + $3.99 shipping.

They have several more used ones for under $10.00
Just search in the books category for the title, and select used,
and they will pop-up.

National Electric Code specifies either coax or insulators when going through a wall. I guess ladder line would be okay "insulation" at lower power although I do not know whether or not it would satisfy the NEC. Technically, I would think not. At higher power, I believe you need a gap to combustible materials (wood).

Probably a insignificant issue but you would probably have an impedance bump when the wood got wet.

I have successfully removed the glass, replaced it with Plexiglas, run the wire though it, years
later I removed the Plexiglas, and re-glazed the window with the original glass.
My pappy taught me how to glaze windows when I was a lad.

21080. Antenna Mast

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-08 03:03:29 UTC
From: Benjamin Straw
Topic: 4830 Message: 21080

Hey guys I have a question I got my hands on five, six foot Lay-up Sticks (
http://www.jamesonllc.com/construction/products/overhead---aerial-construction-tools/fiberglass-lay-up-sticks-pruner-poles
).
I am currently using three of them as a mast attached to my house. My current antenna is a home made ground plane, which is on top of a 3 foot long PVC pipe. The pipe is attached to the lay-up sitck via hose clamps. I'm planning on putting a new antenna this week and am worried about the aluminum tip on the lay, should I cut it off before attaching the new antenna? Or do you think it will be fine?
Thank You, Ben

Hello all,

I have tried to use EZNEC that came with the ARRL antenna book and I have tried the MMANA-Gal (Hope that's right).

As an amateur operator I am not an appliance operator and I have tried to model my antenna myself, which I think I did right, and that is where my dilemma comes in. I was wondering if I could set up a sched with someone that could talk me through either one or both the programs so that I can model my doublet.

If I was going to make such a feedthrough panel, rather than wood [even ash or oak requires regular painting and maintenance], I would use one of those picnic table/decking planks made out of recycled bleach bottles [I think] from the "big orange box store". Perhaps slightly spendy, but one 8-footer ought to be good for a couple lifetimes.

Since I own my home [or rather the mortgage holder and tax collector let me cling to that delusion HI HI] and the house has old cheap-when-new-30-years-ago single-pane vinyl replacement windows inside the original 100-year-old wooden window casings, and since the el-cheapo vinyl windows are slated for re-replacement anyway, in the meantime I just drill the original wooden window frame with an aircraft extension drill [and a big smile at the lack of landlord or property manager or HOA to object].

The original wooden casings will be aluminum-wrapped when we get our new windows, so "all sins will covered". There are a number of Amish craftsmen in the replacement window business in southern Wisconsin who manufacture the vinyl-frame replacement windows they sell and install to your order; shouldn't be any reason I can't get one made with a tall top frame when the time comes for new windows. Even if the original windows were in good shape it wouldn't be difficult to pull a few nails, pull the rails and remove the sashes, essentially disassemble them in place and pop in a vinyl replacement inside the wooden casing as described; then I could always reassemble the original window sashes back in place when it came time to sell the house.

But then, I am extremely fortunate, my YL/future-XYL doesn't care where I drill or whatever, ever since I bored 5 each 1-1/4" holes in the living room floor for her monster aquarium's plumbing to the filter sump in the basement; when the plaster is replaced the pipes will run inside the wall behind a removable panel of wainscoting. Thank Providence for balloon framing with it's 20-foot-plus wall studs rather than the newer stack-wall-on-top-of-floor kind...rebuilding a hundred-year-old foreclosure can definitely be a royal PITA but it DOES have it's advantages...

#1 - the National Electric Code requires either insulators or coax (at least it used to, I assume it still does)

#2 - a bare 2x4 will absorb water and be a poor insulator when it rains.
If you are going to ignore #1, at least use some heavily insulated wire
(like RG-8 coax center conductor) for going through the 2x4.

Good points. Now that I think of it, the MFJ feed-through uses
feed-through insulators with threaded rods running through them.

It is perfectly OK to operate with a maximum plate input power of 1,000 Watts (as a general and
above) which will certainly limit your *am PEP output power* to well under 1,500 Watts PEP. (more
like 800 Watts)

It is perfectly OK to operate with a maximum plate input power of 500 Watts (as a general and
above) which will certainly limit your *am PEP output power* to well under 1,500 Watts PEP. (more
like 400 Watts)

It is perfectly OK to operate with a maximum plate input power of 50 Watts (as a general and
above) which will certainly limit your *am PEP output power* to well under 1,500 Watts PEP. (more
like 40 Watts)

The output of your modulator is part of the plate input power of your final RF stage.\
I said nothing about the carrier power, just: "with 1,000 Watts input."

21088. Dual band inductively loaded dipoles

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-08 16:08:45 UTC
From: Richard
Topic: 21088 Message: 21088

Hi
Just joined the list.
Has anyone tried the design for a dual band inductively loaded dipoles as per the 2011 11th edition of the RSGB Radio communications handbook ?
The reason I ask is that the design on page 15.7 was originally in Rad comm few years ago, and I was
using it with a open ladder feeder and an ATU. That worked reasonably well, but after not using it for a
couple of years it was getting hard to resonate, on investigation I found the solder joints on the
loading coils had broken.
When remaking it I used the dimensions from the Handbook 16' 8" each side with 47uH coils and 2' 9" at
the hot end the other side of the inductors.
I got it up this morning and it resonated at 15.2 MHz and 7.55 MHz, I had to cut a lot off the original
length to use the dimensions given in the 2011 handbook.

2'9" 47uH 16'9" feedpoint 16'9" 47uH 2' 9"

----~~~~~---------- ----------~~~~~----

Is anyone familiar with this design and an idea what the correct length should be ?.
I can only manage to get this about 30' above ground.

thanks

21095. Need help with analizing data

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-09 01:58:44 UTC
From: Don
Topic: 21095 Message: 21095

Gents,

I have just uploaded my loop data to the files section under the folder titled "Need Help With Data".

Basically I have pulled the loop down and used an antenna launcher to get it higher in the air between 25 to 40 feet now.

What I am asking is for someone who knows how to look at the numbers help me understand what I need to do next to get better SWR and performance.

The first loop paced off to be about 600 ft, however after putting it up in the trees I needed to add 150 ft to use the trees properly and it should be 750 ft but my data suggests that it is 402 feet.

Another issue is that it does not hear as well as my dipole based on the S meter of the radio plus signal reports. What it does do well is blank out local noise and I can hear signals close to the noise floor with the loop that I can not hear with the dipole due to noise.

Also the feedline is between 50 and 60 ft of 450 0hm ladder line to a 1:1 current balun to 25 ft of coax going to the tuner.

Please any suggestions on what I need to look at would be greatly appreciated. As I believe that the loop should be better at TX and RX for 160m, 80m and 40m if I can get it sorted out.

Thanks KD8NNU Don

21097. Dual Band J Pole

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-09 05:50:19 UTC
From: Allan
Topic: 21097 Message: 21097

I have a OSJ146/440 dual band antenna manufactored by Arrow Antennas and have a couple of general questions.

1. What would be the optimum height requirement for the antenna?
And
2. Would it really matter if the antenna is going E/W or N/S

I currently have the antenna up about 14'-15' and it's pointing N/S I guess you could say.

I'm not having any issues with it but I was just wondering if I should go higher or if the antenna would be better pointing an E/W direction

Thanks

On vhf/uhf, the higher the better, subject to additional feedline losses. I've never heard of anyone complaining that their 2m antenna was too high.

OTOH, if it is working for what you want (e.g. local repeaters), then it's current height is okay.

I don't understand your directional question. It looks like an omni directional radiator.

It should be as high as you can get it, within reason , VHF/UHF FM is line of sight so it needs to be in the clear of surrounding interference. Too far away from the radio and or the wrong coax will cause more loss than the height can gain. It should be fed with a minimum of RG-8 type, IMO.

> 2. Would it really matter if the antenna is going E/W or N/S

As far as I know it is a completely omnidirectional

fwiw.

I saw this on their website. Hope it helps.
LC160 indicated wire length is 100ft?

http://www.spiromfg.com/parts.htm

ANTENNA SHORTENERS -- Shorten your Antenna over 40%

Perfect for limited Space applications. Used in series with the antenna

elements to reduce the physical length. Housed in weatherproof, sealed

enclosures, same as our antenna traps. NO periodic cleaning is required.

 Built for years of trouble-free service. Instructions included. Sold

only in pairs.
MODEL For Band (meters) Finished Dipole overall length (ft)

Price per pair
LC-40 40 38 $37.00
LC-80 75/80 69 $38.00
LC-160 160 100 $40.00

From: Peter Laws
Topic: 21089 Message: 21104

I've had three different Spi-Ro trap dipoles over the years. They used to answer the phone at least, even if whoever answered was grumpy. In the last few years, they only take your money - no customer service at all. Basically, as-is, where-is.

But ... I've got no complaints about the antennas. Traps finally went bad on my D-56 (5 bands, 6 traps), but given that it was in service for most of 16 years, I'm not unhappy. Got two WASes and most of, maybe all, of DXCC (the first 100, anyway) with it.

John, I have an R7 and I have found about three different manuals online. There are some slight differences in trap design, and some spacing dimensions are different. I think you can ID which you have by looking at how the traps look in the diagram. I can't remember specifics, but it will make a difference in setup.

BTW, I spent 2-1/2 wonderful years at Hickam, way back when...

21107. The G4ZU Bird Yagi for 10m

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-09 17:16:16 UTC
From: Mike Rodgers
Topic: 21107 Message: 21107

http://www.qsl.net/rz1zr/antenny/bag/bag.html

I built the above mentioned antenna which is a wire beam 3 element. It is a spreader design similar to a quad element laid flat. The dipole driven element goes across the center and director and reflector or tied to or part of the perimeter sting or rope.
I used 1/2 sprinkler PVC shedule 80 and had to guy from above. Fiberglass spreaders would be better.

Unfortunately I don't have a dipole or Antron 99 to compare it to. I'm using a
80m delta loop here and for several months have had 4-5 s unit noise which upsets me to no end.

In my situation this antenna has been a good noticeable improvement. It is slightly quieter about 1s unit now at
25'. It was 2 s unit quieter on 8' test pole but the big thing is a much better signal to noise ratio. It seems to bring signal out of the noise.

It's hard to tell with the band fluctuating but it doesn't seem to have much directionality so I can't honestly say a rotatable dipole would be much different. The extended double zepp as a rotatable dipole looks interesting.

This antenna was published in the ARRL Antenna Compendium Vol 2 I believe in 1959. Thanks Ken for providing me that resource to double check boom length. Boom length is 12'
Driven element spreader 16'6"

This has been a improvement for me and I just wanted to share this lest the antenna be forgotten.

On 11 m it's often called a "skypper" and there is a utube video of a 5 min
Assembly which shows what it should look like. Mine didn't turn out that nice.
I should have used fiberglass.

Oh yeah, with the price of materials and anything metal getting quite high, it's not as economical as it once was.
I spent $60-$80.

Unless you are doing CW or SSB on those bands, it should be pointing UP, not E/W or N/S. Vertical, not horizontal.

The position of the smaller stubs (the "J" matching sections) around the main rod, does not matter.

Andy

Anyone who actually looked at this ant, I have one, would understand the question better. The way it is constructed, everything lines up horizontally, like the stuff was lined up on on a 2X4. It is also built incredibly well and serious heavy duty stuff. A bargain at $40. Less than 5 minutes assembly time.

You can use the elements to make 2 meter and 440 yagis. Just Google for plans for those antennas.

Not much use for those elements other than those bands as they are too short for other bands.

Send this review to a friend
Works well and fits my QTH
Time owned: 0 to 3 months
The Spi-Ro LS-160K with the PB-1-C balun works well at my
QTH. The instructions say to just cut your ANT wire in four 25' pieces.
There was no info about how to connect the wires to the brass ends with
the plain screws. I made one simple loop and soldered the wire to
itself.

I was surprised that the ANT works so well with no tuner. Mine is
resonant at 1.818 which is perfect for the CW group I wanted to join at
night. With a simple tuner it tunes the whole band.

The balun and traps seem to be very well made, however it has (a) no
strain relief and (b) no locking mechanism for the plain slot head brass
screws. I would like to hear from other owners about how they fastened
their ANT wires to the brass fittings. I thought about using some sort
of solder-on or crimp-on lug. Maybe I will have to do that if my
current setup doesn't last all winter.

I would recommend this ANT based on it's ease of construction and performance.

21117. Open stub J-pole

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-09 22:25:34 UTC
From: radiotech750
Topic: 21117 Message: 21117

I just made an open stub j-pole for 2/440. My question is... can it be mounted directly to a metal mast or does it need to be insulated from the mast/
Thanks in advance

Ernie

Great! Might be easier that way, measuring plate current with a home brew sweep tube linear. Still have some left collecting dust.

Brian KA9EGW wrote:

"It is perfectly OK to operate with a maximum plate input power of 1,000 Watts (as a general and above) which will certainly limit your *am PEP output power* to well under 1,500 Watts PEP. (more like 800 Watts)"

Brian, please help my understanding.

1kW DC input, figuring a plate efficiency of 50% (a reasonable figure... some have folks have gotten up to 60 or so per cent, IRRC) would still yield 500 watts RF out.
Now, the figure of PEP equaling 4 x the unmodulated carrier power would make the PEP in that case to be 2000 Watts... correct?

So, unless you're running a really ineffiecient final stage... say, 37.5% efficiency at 1kW in, you'd be over the limit set by FCC 97.313.
Which, incidentally does not mention DC input, or a 1000 Watt power level.

Any thoughts?

Stan

Topic: 389 Message: 21121

Hello folks!

I'm new here, and getting the HF part of my shack together, including antennas- a long wire and a coil with a telescoping whip. This is somewhat humble beginnings, and one reason why I wanted to join Ham-Antennas. I'm looking forward to building and experimenting with antennas, and getting on HF to the fullest extent that I can.

I was given my first legal limit antenna tuner by a wonderful friend, Elmer and baby brother. He had been watching for one for me, and ran across an MFJ-962 just like his. The 962 he has was his first, and it was a circa 1979 model. It had served him well for many years, and he determined I should start out the same way.

The real kicker was not being able to find a manual for it. Even MFJ didn't have an archived copy. Looking on eBay and other places yielded no success. Plenty of 962-B, 962-C and 962-D manuals but not one 962 "no letter" Grandpa model manual. But a copy materialized, and it wound up emailed to me by little bro.

In the spirit of sharing information about this great chunk of equipment I offer it here in the Files section, with all credit to
MFJ, the manufacturer of the 962 tuner series, and holder of all rights pertaining to product information. I present it merely in the
interest of promoting the use of the device in our hobby of Amateur
Radio, with an archive .pdf copy sent to MFJ for the purpose of making this information available to future owners and users of the original 962.

I'm looking forward to meeting folks here, and learning a lot of things. And finishing studying for my Extra upgrade. Happy holidays and 73 de KE5LIB!!

Mark

21123. Nested Delta loops and mult-band dipoles

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-10 12:19:53 UTC
From: Richard
Topic: 21123 Message: 21123

Hi
When nesting Delta loops, do you common the feed point before the 4:1 balun or after it, that would be
combining the two 50 ohm feeds,
or using transmission lines the match the combined 32 ohm (16ohm back up to 50 ohm).

The 10 mtr D loop works fine, I dont want to lose too much of its performance, nesting would be for 20
mtrs and 10 mtrs.

After measuring out the yard I can put up a half wave dipole on 40 mtrs, 30' above ground level. If I use
that as a multiband dipole by adding a 17 mtr dipole from the feed-point, what separation is advised
between the two non harmonically related dipoles.

Thanks

Cool, it looks like a 20 meter three element beam that is back packable, all you need is rock
with a vertical hole in it, about this big around. The construction places the wires under tension
so the winds won't change the tuning.

Nothing spezial
Most dx-peditions use this design ... formerly known as spider-beam
(google it!)
Build from fiber-glass tubing and wire
Can be built as 3 or 5 band version
Even making it bigger and including 30 and/or 40m can be done

Ernie

Sigi is very helpful and has good ideas but I think he needs to look at you antenna schematic. A J-pole type antenna can work on a grounded mast, it is recommended to use a coaxial choke just under the antenna to prevent RF flow back down the line. Five to seven wraps of RG-8X is common then RG-8 size to the radio.
The slim-jim style j-poles are recommended to be on a non conductive mast. I have built both kinds and all my j-poles have been with a common mast/ main element. No one has ever had a problem with one.
The copper slim jims have used a 1/2 fiberglass rod as a mount, if it was made from 450 ohm line then I used PVC pipe.

Try it grounded and see of you like it, if you think it is substandard use many wrap of pop bottle plastic (or some such) to wrap around the mast under the clamps to insulate it. (tape the
plastic wraps down)

Date: 2011-12-10 16:06:26 UTC
From: Robert Costa, KB6QXM
Topic: 21133 Message: 21133

All,

Now that I have obtained my test bed fan dipole, I need to ask the group some questions.

I will be adding many additional parallel wires to the Alpha-Delta DX-lb to add 60 meters along with all of the WARC bands, I need to understand the pros and cons of larger gauge wire, solid core versus stranded.

Alpha Delta uses solid core 12 gauge for their antennas.

I like the look and the rigid nature of solid core 12 gauge. Considering the narrow bandwidth of 60, 30, 17 and 12, is the large solid core wire needed?

Any thoughts?

It's not quite like a hex beam.
It's a 3 el beam.
The driven element is straight and the director and reflector elements are bent.

Do not only check swr ... check also signal(s) from some repeaters ... maybe swr does not change much but you can have high angle radiation if pole does reonate and is connected
Wrapping coax does eliminate rf current on shield ... but isolating the pole is another thing

Sigi, I'm sorry you thought my post was nothing special.

As to your comment about it formally known as a spiderbeam, the website acknowledges the original design belongs g4zu.

From: Richard Schmuke
Topic: 21133 Message: 21138

I don't think you will find much band width difference at these HF frequencies. The 12ga is needed for support as the main wire. Any size wire , solid or stranded that does not break will work as the fan. It must be within reason, 30 gage and up might not hold a bird, 16, 18 or so would work.

Rich , Kd0zz

From: ham-antennas@yahoogroups.com [mailto:ham-antennas@yahoogroups.com] On Behalf Of Robert Costa, KB6QXM

To: ham-antennas@yahoogroups.com
Subject: [ham-antennas] Wire size and solid versus stranded

All,

Now that I have obtained my test bed fan dipole, I need to ask the group some questions.

I will be adding many additional parallel wires to the Alpha-Delta DX-lb to add 60 meters along with all of the WARC bands, I need to understand the pros and cons of larger gauge wire, solid core versus stranded.

Alpha Delta uses solid core 12 gauge for their antennas.

I like the look and the rigid nature of solid core 12 gauge. Considering the narrow bandwidth of 60, 30, 17 and 12, is the large solid core wire needed?

Any thoughts?

From: Richard Schmuke
Topic: 21117 Message: 21139

Well I think both ways would work, if you don't get RF feedback then you don't need a choke.

Where did you get the stud mount SO-239? I have some with a stud but the stud is way too small to support the vertical, it is only a 3mm stud.

Did you drill and tap the rod or find some heavy wall tubing. I like making things myself. I have often wondered about this design myself because on the 2M monobander they feed the long element and they would be a large load on the SO-239, on the dual antenna they feed the stub.

Date: 2011-12-10 23:02:23 UTC
From: John Parker
Topic: 21122 Message: 21153

Aloha everyone!

I have done an inventory of my Cushcraft R-7. Thanks to Michael KE7SBE and Time N3XX for the URL links.

It looks like my MN7 Box needs to be replaced as it has a huge crack on the back side and broken through. I have found an exact replacement for that for $5.00

But, the condition of the antenna itself looks like it needs some maintenance, i.e. Rust spots, etc.

Should I use something to sand that off and do I need to place any kind of protective coating on the antenna? I would imagine that due to the climate here on Oahu, this will be a constant battle for me.

Any suggestions?

Also, totally clueless about mounting, transmission line to run to my xcvr, etc. I guess this is why it has taken me 11 years since I¹ve been licensed to get this far!

Any help would be appreciated! I have set a time frame of 2 months, to get this antenna, cleaned up, enclosure replaced and everything mounted and hooked up to my TS-850.

In general, it should be grounded for lightning protection.

Mounted to the metal mast (the mast is grounded) it will be grounded! I am
just trying to find out if it can be bolted directly to the mast or needs
insulated from the mast!

From: fred
Topic: 21133 Message: 21156

Stranded wire will take more abuse (bending) than solid wire will before it breaks , also is easier to coil if you need to store the antenna . I used # 12 THNN for the 75/80 metre dipole as it was all that I had enough of . the triband dipole 10 , 20 and 40 metres is # 14 THNN . has been up at this QTH since 2003 with no problems or wire breakage yet , the ropes are a different matter . all antennas are wide banded enough to cover the entire general class portion without a tuner except the 10 metre dipole .

Smooth sanding for cleaning is okay as long as you do NOT use steel wool or similar ... no metallic abrasive for that or it will re-corrode even faster

Steel wool will let some small steel parts in the surface ... and so it will re-corrode caused by chemical element building on the contact area

All of my VHF/UHF vertical antennas are attached to a metal pole and that pole is either on top of concrete or stuck in the dirt. They all work very well.

From: N3XX
Topic: 21122 Message: 21159

Hi John,

If the MN7 box is cracked, I would look very closely at the matching network inside for any signs of damage or overheating.

I would use fine sand paper or emery paper to get any rust/corrosion off of any metalic mating surfaces. Don't get too concerned about areas that don't make contact with other parts.

Important - get some Penetrox and apply to any metal mating surfaces as you assemble the antenna (DX Engineering & many other places sell it - Google will find many sources). Connections will be good for many years if you use this.

I have never owned an R7, and looking at the manual I don't see any suggestion about how high to mount it. I also looked at the R8 manual and it's suggested to mount the R8 at least 10' above ground. Just don't know about the R7.
Also, most verticals require radials on or in the ground for proper operation. But I see no mention of this in the R7 manual. So maybe it is designed for operation without ground radials. Hopefully someone who has actually owned an R7 can point you in the right direction here.

I always use RG-8 coax, but I run an amp most of the time, so it's a requirement. If you are only going feed the antenna with 100W from the xcvr, and not mounting the antenna more than a hundred feet away, RG-8X should be fine (and less costly). In this case use the same PL-259 connectors that you would have for the RG-8, but an adapter for the smaller RG-8X cable will be required. Sorry I don't have the part number for the adapter, since I never use them.

Hope this helps & good luck with getting on the air.

73,
Tim - N3XX

Aloha everyone!

I have done an inventory of my Cushcraft R-7. Thanks to Michael KE7SBE and Time N3XX for the URL links.

It looks like my MN7 Box needs to be replaced as it has a huge crack on the back side and broken through. I have found an exact replacement for that for $5.00

But, the condition of the antenna itself looks like it needs some maintenance, i.e. Rust spots, etc.

Should I use something to sand that off and do I need to place any kind of protective coating on the antenna? I would imagine that due to the climate here on Oahu, this will be a constant battle for me.

Any suggestions?

Also, totally clueless about mounting, transmission line to run to my xcvr, etc. I guess this is why it has taken me 11 years since I?ve been licensed to get this far!

Any help would be appreciated! I have set a time frame of 2 months, to get this antenna, cleaned up, enclosure replaced and everything mounted and hooked up to my TS-850.

I used to own a Cushcraft vertical either an R6 or R7. There were radials but they were not ground radials. I gave it to a friend and his buddy said he could leave the radials off and when he took them off the antenna didn’t work very well. He finally contacted the company and they told him they had to be on there so he put them on and now it works great.

The cushcraft antennas (the verticals) are off center fed halfwave dipoles

Fed close to one end it has about 200 ohms impedance or something liker that

That is the reason for the step up transformer and the choke at the base

If you would leave off the short radials it would be as you would cut a longer end away from a dipole ... result ... off resonance ... not well matched to coax ... wont work as suggested !

I modelled it in mmana (or a very close design) ... and without these short stingers the feed-point has nothing to work against (coax is isolated with the built-in choke) so there is simply half of the antenna missing

Or in an off center fed dipole (widomlike or like fd4 or similar) it would be as you would let away the shorter leg

Besides divorce, cutting in the hand while erecting antennas (cutting rope
or wire), falling from a tower, getting a hit from tube amp .... ham radio
is such a dangerous hobby (big grin)

From a place were you not have to worry (northern dl)
No snakes, no spiders,
and as most important thing :
NO THUNDERSTORMS / HURRICANES / TSUNAMI ... etc ....
Flat area from here to cost (abt 150km), no neighbours close (next is a half
mile away) so no man made noise ... ham radio heaven location (ok not as
good as radio arcala *g*)

Mounted to the metal mast (the mast is grounded) it will be grounded! I am just trying to find out if it can be bolted directly to the mast or needs insulated from the mast!

Ernie

_____

Ernie,

Just bolt it direct to the mast. No insulation needed.
These are a DC coupled antenna (like the old Ringo Ranger) and can connect to DC Ground.

Mine is made of hard drawn copper tubing and has been up for 17 years and still going strong.

Put it up and enjoy.

> Any thoughts on the insulated-elements issue? A micro-tutorial on j-pole theory?

A "J" pole antenna is much the same as the old "Zep" antenna.
Both are a dipole antennas (1/2 wl long) fed by a 1/4 wl "stub."
The "Zep" (short for Zeppelin) is generally fed directly into the end of the stub, the "J" pole is
generally fed slightly away from the shorted end of the stub. The old "Zep" antenna were fed from
tube transmitters with excessive tuning capacity, allowing some compensation for antenna irregularities.

The "J" pole antenna is fed a distance from the shorted end of the stub, based on the transmission line's impedance. Close to the short if fed with 50 Ohm cable, up a bit further (from
the short) if fed with 75 Ohm cable, higher (further from the short) if fed with 300, 450 or 600 Ohm
line. The center conductor of the coax can connect to either side of the stub.
The stub serves as an adjustable transformer, to allow correct match to the transmission line.
The bottom of the stub is at zero Ohms while the top is over 10,000 Ohms which nicely matches the
end of a dipole. The connection between a vertically mounted dipole and the stub is a very high
voltage low current area, half way up (1.4 wl) in the center of the dipole the voltage is zero and
the current is at it's maximum. At the top of the dipole is a very high voltage low current area, as
is the other end of the dipole, but the polarity is reversed.
The stub of a "J" pole antenna can be mounted horizontally or vertically. The dipole of a "J" pole
antenna can be mounted horizontally or vertically. The stub and dipole can be mounted the same or

at a 90 degree angle.
Two dipoles can be fed from the opposite terminals of a single stub. (in opposite directions)
This 1 wl long antenna will have 1.8 dB gain over one dipole, not 3 dB. (the dipoles are too close
together, the pattern is not optimum)
VHF and UHF "J" pole antennas frequently have 3 to 6 turns of transmission line coiled just below
the antenna proper as a "poor man's balun" to lesson the effects of the dress of the transmission
line in the match or tuning of the antenna. Ferrite baluns generally perform poorly at VHF and UHF
frequencies.
"J" pole antennas work great from 160 meters to UHF. It's hard to beat a dipole.

Well it is not exactly radio but you can laugh at me if you want to. I had a little problem with my hand. I have worked with machines all my life. I was doing a job on the front door and needed a couple of wood shims. I went to the shop, grabbed a section of 2x6 and cut the shims. I looked at the first one and saw that the edge was rounded like the edge of a 2x6 would be and I wanted all square edges so I quickly picked up the wood to cut one more, ran it thru the saw and cut the end of my finger off.

Now comes the problem, I ran to the house, yelled for the wife to get the car keys and take me to a hospital. Well she did but that mean woman took me to a mental hospital. The closet place that was a regular hospital still had a emergency room but is now the mental facility for a group of hospitals. I can post a picture if needed for you pleasure.

21172. RE: [ham-antennas] Wire size and solid versus stranded

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-11 04:44:27 UTC
From: John P.
Topic: 21133 Message: 21172

Hi,

  I use #14 or #12 stranded and insulated wire. It is not expensive at places like Home Desperation (Depot).

Remember also that the insulation reduces the velocity factor by 3% to 5%.

  I have had great results with a fan dipole for 75, 40 and 20.

  Of course it is still prudent to support no only at the ends but the center.

I don't think you will find much band width difference at these HF

frequencies. The 12ga is needed for support as the main wire. Any size wire

, solid or stranded that does not break will work as the fan. It must be

within reason, 30 gage and up might not hold a bird, 16, 18 or so would

work.

To: ham-antennas@yahoogroups.com

Subject: [ham-antennas] Wire size and solid versus stranded

All,

Now that I have obtained my test bed fan dipole, I need to ask the group

some questions.

I will be adding many additional parallel wires to the Alpha-Delta DX-lb to

add 60 meters along with all of the WARC bands, I need to understand the pros and cons of larger gauge wire, solid core versus stranded.

Alpha Delta uses solid core 12 gauge for their antennas.

I like the look and the rigid nature of solid core 12 gauge. Considering the narrow bandwidth of 60, 30, 17 and 12, is the large solid core wire needed?

Any thoughts?

If you work at a saw NEVER EVER do a "quickly last cut" .... it will most of the time really be your last one if the saw catches your finger(s) OR SOMETHING ELSE!!! (see below)
No need for a picture .... I cut myself in the left leg just below the knee with a CHAIN SAW !!! that was at work ... same thing ... oh lets make a fast cut here and there just at the end of the day ... maybe brain was already on the way home ... who knows ... guess what ... it was no fun to see the red fluid running in my shoes ... and seeing the bone really shocked me!!
But I had luck in that accident ... only skin cut ... nothing important damaged at the leg ... now I have a "zip" below my knee that remembers me to use the safety pants on EVERY cut with the chain saw
Now the safety pants is in a box on-top of the saw ... so whenever I will use the saw I have to take the pants in the hands anyway to get to the saw and then putting your legs in it is no problem :-)

Topic: 21133 Message: 21175

Siegfried,

Thanks for sharing, I only casually use a chain saw, and I think the pants and proper boots are now something that I will have to get before I use the saw again in the future.

I have had a close call once due to stupidity but nothing happened but your warning will be paid attention too.

21176. Static/noise on 2m & 70cm

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-11 14:38:23 UTC
From: Benjamin Straw - KC9UNS
Topic: 21176 Message: 21176

I have an odd problem, about a week ago I noticed severe static/noise on 2 meters and even worse on 70 cm. Here is where it it gets odd it only happens between 10 am and 2 pm then it starts to fade away by 3:30 pm and then all is fine.
I just put up a new antenna with new coax so that has been ruled out and I can talk on local strong repeaters but not the ones on 70cm as the noise sounds like popcorn poping. The only way I can describe this noise/static is if someone who is normally S5 on simplex, is now S7 and is barely readable. A lot of people said it was Christmas lights but it's only during the day. I have unplugged everything in the house, turned off breakers, and even tried another rig and still cant figure it out.
So I ask what do you think it is?
Ben KC9UNS

You don't say if this is on AM, FM, SSB or CW, you don't say if any noise is there with the antenna is disconnected or if it is there with a "rubber ducky" (with adapters) is used on the back
of the radio.

Sorry I just assumed FM because most radios are FM, but yes the noise/static is on FM (BTW the radio is a Kenwood TM-G707).
My HT goes nuts all the time(some RFI in the shack) but not as bad as of late. There are no adapters attached the coax other than when I do connect the ht to the outdoor antenna. And like I said in the last email I replaced my antenna and coax just a few days ago, I went from a homemade ground plane to a 17ft vertical and went from rg8x to rg213 coax

It takes a strong noise signal to cause noise over a FM signal. You need to be the detective.
A pocket am receiver (or larger as do a few HAM handy talkeys that have very wide band am receivers
in them) frequently have a "ferrite loop" antenna that can be quite directional, one of these can be
used to locate the source of noise if yo slowly walk around the block listening and pointing.
When the axis of the "ferrite loop" antenna is aimed at the noise source the nose will be nulled.

Do you have cable TV in your area? I had leakage from the cable system leaking into 2m and 440. I was getting a S9+60db signal on a Kenwood TS-2000 from the cable. I watched my radio as the cable tech tightened the connection on the cable and interference went below the noise level. Google the cable network frequencies and see which channel you are hearing.

If it is always at certain hours, that may indicate a business. Are there any medical offices near you (including chiropractic)? Some of their equipment may emit RFI.

Do you receive this on your HT if it is hooked up to the antenna?

If all else fails, you may want to talk to your local power company. When I was having problems with RFI, they sent out a troubleshooter with directional equipment and located the problem. It turned out to be a neighbor running large woodworking equipment.

A fellow I worked with told about the large computer they always had crashing at 1 pm every Friday. One time at lunch they were talking with some military guys from the base across the road. They happened to mention that they tested a certain radar unit once a week....yep, Fridays at 1pm.

I had the same thing! I lived close to a hospital and from 9-3 static! Come to find out it was a unshielded portable power supply for some of their med equipment!

Any solar panels new in the near area???
Could be the power inverter ...
From 10-11 am sun has enough energy for inverter to start ... and after a
few hours inverter switches off again ...
Or could be from the pump of a thermo solar panel

You really need to listen to the noise on either an AM or SSB Rx. The limiting
in the FM IF will distort the noise, making it hard to identify.

That sounds horrible. I always keep a death grip on my saw but I guess I should get the pants. I just had to get a carburetor kit and fuel lines for my Stihl 028 super, it is a great saw but the gas over here destroys the diaphragms with the alcohol they add. I am waiting for my hand to heal a little more before I fire it up.

21190. Ground wire solder lugs

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-11 22:21:33 UTC
From: fardds
Topic: 21190 Message: 21190

I've bought some soft-drawn, annealed, solid copper #6 wire to use to connect my ground rods to a 30" Rohn tower as well as to bring into the shack for an earth ground. Will also use it to place an earth ground on a Cushcraft R6000.

Anyone know where I can find solder lugs to fit this size wire? I see pinch connectors, but prefer to get a solid, durable connection.

Thanks in advance

Fred (KX3R)

From: Jim Whitaker
Topic: 21192 Message: 21192

Hey thanks guys for the balun help. I wound it with as many turns as would fit on a T200-2B core (about 24, 12 on each side). Oh yeah and who ever said that Teflon wire is hard to deal with, you were right. It was like wrapping a worm around a snake! I haven't been able to test it yet still waiting for R&L to ship my analyzer.

Tnx DE Jim N8XYN K

Fred,

I believe that a mechanical connection is preferred vs solder, which will fail with a lightning strike.

Any electrical supply shop (or Lowes, HD, etc.) should have screw down brass or bronze lugs for use in electrical boxes.

The other thing that I have done is to beat down a piece of copper tubing onto the wire, and then flatten the rest of it and drill a hole in it.

Try a Burndy or Thomas and Betts catalogue for #6 lugs

Talk to your local electrician he probably has the die set for installation.

Burndy also makes a pipe clamp with a flat surface to accept a standard lug we used these in a Telco installation to ground water pipes to the central office ground bus.

Subject: [ham-antennas] Ground wire solder lugs

I've bought some soft-drawn, annealed, solid copper #6 wire to use to connect my ground rods to a 30" Rohn tower as well as to bring into the shack for an earth ground. Will also use it to place an earth ground on a Cushcraft R6000.

Anyone know where I can find solder lugs to fit this size wire? I see pinch connectors, but prefer to get a solid, durable connection.

Thanks in advance

Fred (KX3R)

these lugs should be compression type using a die set they survive lightning strikes better than mechanical bolt type that corrode and may loosen with time

Try a Burndy or Thomas and Betts catalogue for #6 lugs

Talk to your local electrician he probably has the die set for installation.

Burndy also makes a pipe clamp with a flat surface to accept a standard lug we used these in a Telco installation to ground water pipes to the central office ground bus.

Jim, I am the guy who told you how nice it is to use Teflon coated wire. I held the wire spacing with little alligator clamps and the wire on the toroid with little battery clamps while to epoxy dries. Here is a show and tell picture of that and other baluns I have tried. It has to be done in steps or the snake will get away.

Hey thanks guys for the balun help. I wound it with as many turns as would fit on a T200-2B core (about 24, 12 on each side). Oh yeah and who ever said that Teflon wire is hard to deal with, you were right. It was like wrapping a worm around a snake! I haven't been able to test it yet still waiting for R&L to ship my analyzer.

this reminds me of noise problems I found in the past.

One was way back, and I tracked it down using a DF loop with an HT,
turned out to be an older color TV that had a problem with the
Horizontal output circuit. generated noise like you wouldn't believe.
later on, I found that on 2 meters I got interference that centered
on 145.250 Mhz, turned out to be leakage from cable splitters where
things were not terminated properly.
I also used to get noise when I went into certain businesses. Was
generated by cheaply built computers.
And another I got intermittently on HF. I tracked it by walking
around the area with a handheld radio that has HF RX. It turned out to
be the rat Shack switching power supply I had. did not bother 2 meter
FM. I sold it on Ebay with the caveat that it had the noise problem.

The fact that it is only in a certain time frame does seem that it is
most likely a poorly built computer, or something else that is only
used at certain hours.

Tracking it down, a handy item would be a tape measure yagi. I built
one for 2 meters, that was simple and effective from an online
article.
uses PVC, tape from a super cheap tape measure, a section of copper
wire for a hairpin matching device, and a length of RG58 coax.
It can also be used for field days and camping out.
One thing I did was to solder the coax and hairpin connections to the
tape. Scrape the paint off and use a good soldering gun.
I like my old Wellers. Bought a rat shack unit, does not do as well.
Are/were other brands out there. Wen comes to mind.
the yagi is 3 element, director, reflector and driven element. And
can, if built correctly, be used to transmit with an HT or anything
under 40-50 watts. when not in use, the elements can be rolled up so
it takes little space.
Also great for fox hunting...

Rich, I can see why you'd want to use solid magnet wire. I just held it in place under tension provided by teeth! The hard part, the spot where 3 hands would have helped was tying down the ends with nylon ties. I went through about 5 of them on one set of wire ends. Funny thing is I've already learned something. My current antenna (purchased) is a 40 meter ocfd. It tests as an open circuit with an ohm meter. It's SUPPOSED to have a 4:1 at the feed point. The balun I wound tested as a short circuit like I expected...hum...make you wonder what's in that box up there in the air.

Larry, I don't remember the price because I have bought several of different sizes thru the years. 130's 157 and 200. The reason they look like your Amidon is because that is the brand I buy. I get them at my local electronics emporium, http://www.gatewaycatalog.com/. In St. Louis county.

The prices are about the same as you see on the net from other places but I don't pay shipping when I stop at the store and pick up some PL-259's and SO-239's, carbon 47 and 200 ohm resistors for testing the baluns and stuff.

If you want to buy them on line try the toroid king at

Hi Ben and Everyone else,
Have you tried unplugging the antenna from your radio to see if you still get noise? If RFI is still present your source could be close.

You have a good list of possible RFI sources thanks to everyone. From my own experience, I can add a fax machine in my home office. An avid DXer friend had problems with a cracked high tension insulator and utility line transformer but the worst for him was some grow lights at a neighbor's several doors down.

A stroll or drive around your neighborhood with your HT when RFI is present my give you some insight.

Good Luck and Merry Christmas,

Jon, N8YSS

Solder the wire into copper tubing. Flatten the tubing and drill the bolt
pass thru hole.
Or crimp the flattenned tubing in the clamp fitting on the ground rod.

de n8xyn k

Jim, you got the old man thinking and I came up blank so I got my book out by Jerry Sevick, W2FMI, the master on baluns. I could not find any 4:1 in his book that would be open circuit. The only open one was a 1:1 wound with coax on a toroid ...hum...make you wonder what's in that box up there in the air.

Note: Teflon wire is better for hi-voltage and high power, so you should be good for a full gallon . I even put some Teflon wire inside a coil of copper tubing for a filament/grid fed amplifier but that's different reflector story.

For whoever needs to know when I worked with rod type baluns I did wrap the rods with Teflon tape for insulation when I used magnet single coat wire because they don't have the clear coat epoxy on then like the Amidon's toroids do. To hold spacing on the magnet wire I used monofilament fishing line, spring clamps, then epoxy on the wire. For a 4:1 current balun I had better final readings with a duel rod type. You can get Russian military surplus 10mm x 200mm rods from E-Bay. Rods are cheap but shipping is high from the Ukraine, I was happy with what I got.

I also used zip cord speaker wire, another hint from Jerry Sevicks's book. Easy to work with , easy to get compared to some magnet wire (even Wal-Mart has it) and does not have the evil spring of Teflon coated wire and is color coded for ID. Here is a switchable 1:1 or 4:1 balun made with it.

I've heard that some vendors just put a few snap-on toroids on the coax inside a box and call it a balun. Of course, it isn't.

Anybody near you have a PV solar system? I've heard that the inverters can
be very noisy, and it would correlate with the period of strongest sunshine.

If you test with a DC ohm meter it will show as a short but the inductance at RF will make it totally different. My advice would be to install it and try it out on the air.

(I've heard that some vendors just put a few snap-on toroids on the coax
inside a box and call it a balun. Of course, it isn't.)

Some how I don’t find that hard to believe, snake oil salesmen and all. I’ve disassembled a lot of things in my life and noticed a general trend toward poor construction over the past decade.

21211. 500' feed lines , Part 2

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-12 20:15:04 UTC
From: Artekmedia
Topic: 21211 Message: 21211

Earlier I posted on the group asking for experience with very long (a 100' is nothing) open wire feed lines sighting a faintly remember article in 73 (which I never did find) that used 4 wires instead of 2 and how you match that to 50 ohms on each end

To date these are the requirements and what I have gleaned so far and a plan is slowly forming

1) This will be the main feed line for all antennas from 160M -10M
2) The antenna farm is about 500' away from the shack
3) The ability to match to 50 ohm line on both ends is a necessity. Tower and beam on on end, typical transceiver on the other
4) Antenna tuners are not an option for many reasons so the system must be broad band and very low loss

Here are some of the things I have discovered so far
1) a 500' open wire 600 ohm line would be reasonable to assemble and not terribly expensive, losses of less than .25 db at 30 MHz are not unrealistic to expect.
2) The 600 ohm line would require a 16:1 balun to convert it to 50 ohms at both ends. Truly flat low loss 16:1 baluns that cover the entire frequency range are hard to build with most designs covering 1.8 to 14 MHZ or 14 MHZ to 30 MHz well but not the full range, Multi-balun designs using a 1:4 feeding a 1:3 often using 2 or 3 cores seem to be one possible solution but at a higher insertion loss, and broad band performance appears to be tricky
3) I now suspect the earlier article which used 4 wires which were chosen to lower the feed line impedance to 200 ohms for an easier broad band match using 4:1 baluns which are easier to construct and are better behaved over the frequency range than the 16:1 baluns

Next thought exercise

1) construct a 4 wire 200hm line. This requires spacing on the order of 1.75" using #12. probably needs lots of spacers to be well behaved.

2) Another possibility is to use two 450 ohm ladder lines spaced comfortably apart and connected in parallel (effectively giving 225 ohms . I am told that the #14 version of the 450ohm line is actually closer to 400ohms ...can anyone verify this ?

Anyone have loss figures/100 ft for the #14-450 ohm line at 30 MHz?

More thoughts? Suggestions?

Correction that should be a 12:1 balun sited below (16:1 is for 800 OHM LINE) ..in either case still a challenge

FWIW, DX Engineering sells a setup exactly like that, two baluns and as much ladder line as you would like. You might check into their design for more information.

21217. Re: [ham-antennas] 500' feed lines , Part 2

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-12 23:31:36 UTC
From: Artekmedia
Topic: 21211 Message: 21217

FWIW ....apparently it is worth quite a lot ..the DXE solution for 500 ft with the two transformer is $545 ($300 of which is for the baluns)!!!

Don't get me wrong I love DXE and have bought from them on occasion in the past and I am a satisfied customer...but the cost of the two baluns at $150 each is more than my Scottish ancestry gene pool can wrap it's mind around.

One troubling thing about the DXE system is they quote .7db total loss for the two baluns plus 500' of line but dont say at what frequency. They quote the ARRL handbook as the source of the loss figure which leads me to believe this must be at 7 MHz, because at 30 MHz the ARRL handbook would gives .8db for 500' of window line. if I add another .2 db per balun I am now up to 1.2db total loss at 30 MHz (still good compared to coax at that length). Now I am the first person to argue who cares about .5dB, but the lack of full disclosure on DXE's part in their very detailed 5 page PDF document about the system seems just a bit disingenuous.

To answer one of my other questions though they do state that their 450 OHM Window line is really 400 OHM nominal impedance

I have an email into them for clarification on the loss figures

Anyone remember these?
http://sutherland.blogs.com/photos/uncategorized/emew6po2_2.jpg

Now I would assume, that the reflector could be replaced with a solid
sheet of metal true?

It is simply an array of 3 element yagis. The reflector elements can usually be replaced with
almost any reflector, but the tuned rods offer the least wind resistance.
This appears to be a "branch" array and not a collinear anything.

And the QRO amp cost?

To: ham-antennas@yahoogroups.com
From: nr1dx@...t
Date: Mon, 12 Dec 2011 17:31:36 -0600
Subject: Re: [ham-antennas] 500' feed lines , Part 2

FWIW ....apparently it is worth quite a lot ..the DXE solution for 500

ft with the two transformer is $545 ($300 of which is for the baluns)!!!

Don't get me wrong I love DXE and have bought from them on occasion in

the past and I am a satisfied customer...but the cost of the two baluns

at $150 each is more than my Scottish ancestry gene pool can wrap it's

mind around.

One troubling thing about the DXE system is they quote .7db total loss

for the two baluns plus 500' of line but dont say at what frequency.

They quote the ARRL handbook as the source of the loss figure which

leads me to believe this must be at 7 MHz, because at 30 MHz the ARRL

handbook would gives .8db for 500' of window line. if I add another .2

db per balun I am now up to 1.2db total loss at 30 MHz (still good

compared to coax at that length). Now I am the first person to argue who

cares about .5dB, but the lack of full disclosure on DXE's part in their

very detailed 5 page PDF document about the system seems just a bit

disingenuous.

To answer one of my other questions though they do state that their 450

OHM Window line is really 400 OHM nominal impedance

I have an email into them for clarification on the loss figures

21221. RE: [ham-antennas] Open stub J-pole

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-13 01:31:02 UTC
From: Richard Schmuke
Topic: 21117 Message: 21221

Ernie, I would sure like to know where you got the SO-239 stub fittings for the antenna you made, the insulating washers should be no problem, I can make them but I am lost about the threaded rod to coax fitting.

Where did you get the stud mount SO-239? I have some with a stud but the stud is way too small to support the vertical, it is only a 3mm stud.

Did you drill and tap the rod or find some heavy wall tubing. I like making things myself. I have often wondered about this design myself because on the 2M monobander they feed the long element and they would be a large load on the SO-239, on the dual antenna they feed the stub.

Rich, Kd0zz

Rich.

Here is a link to the open stub j pole I made. This is not MY antenna. As

you can see it is mounted directly to the mast with NO balun!

http://www.w4cll.com/my_jpole1.htm

Which is correct?

Ernie

> More thoughts? Suggestions?

I would construct 600 Ohm line from "AWG 14 THHN" and "ladder snap" spreaders and I would use a
4:1 balun at each end and see how it performs before doing anything further. The idea of transforming it to 50 Ohms at each end seems quite unnecessary to me. (and over rated)

Two 250 foot packs at $75, I would choose white (and two 500' rolls of THHN, I would choose white) see: http://www.73cnc.com/product_p/ls250.htm

"> Anyone have loss figures/100 ft for the #14-450 ohm line at 30 MHz?"
The losses lower as the impedance increases. (look in old ARRL antenna and handbooks)

Every only time I saw 4 wire open wire feed line there was a 10,000 Watt transmitter feeding it.

Well, im not sure what your trying to accomplish ... more signal to the world? Are you down in a gully?

If your a cloud burner right now and the long run is to get up a hill for better propergation ... what's your priorities at ... keep hro or buy the parts to get better propagation with 100w and later get balun's for the QRO level output. (id keep the amp ... I have a HL2K)

My point is forget the high power balun and get it working- QRO can come later.

What's better 3Kwpropergation into a antenna or 50wthe into

Subject: Re: [ham-antennas] 500' feed lines , Part 2

Bought it over 25 years ago ...don't remember, I am working on the 2nd

set of 3-500's though ..Kind of like my 1996 ford explorer that has

210,000 miles on it ..had it so long cant remember what I paid for it ...

What is your point?

The instructions say to use 25 foot wire segments. So the shortners go in the middle.

no it may look like that,

but this WAS a major player of antenna gain in the 60's and 70's it IS
a collinear array. sometime also extended and expanded. Cushcraft made
thousands of them. And some of the first successful moonbounce contacts
were made using this type of antenna.

I found mine at a truck stop and also have seen them at rad shack. I want to make another OSJ using 3/8" stainless steel tubing. Does anyone know if it would perform the same? Or is aluminum still the best choice?

The drawing for that antenna indicates the SO-239 has a male threaded stud as part of it. The standard one you speak of is a female 3/8x24 for a CB type whip.

I have the SO-239 and 3/8-24 adaptor also, the factory drawing looks like it has a male stud not a 3/8-24 female, I was looking for a SO-239 with a large male stud as a integral part.

SS steel wire would have a difference with a 80M antenna but remember almost all 3 to 4ft whips are 17-7 stainless steel

My first was a 40/80m fan dipole (also works on 15). The yard wasn't big enough so the ends of the 80m section were bent back.

You didn't mention what bands you want or what kind of operation you want. Or what space or supports you have available. Or how much you want to spend. All of those play heavily into any recommendation.

But simple dipoles are a decent way to get started.

Back in 1961 my first antenna was a 300 ohm folded dipole for 40 meters.
made from salvaged TV twin lead

The tank circuit on my home brew single tube transmitter using an 807 as
a xtal controlled oscillator was set up to match the 300ohm line
rather than 50 ohms popular today.

If I were starting out today I would build a skeleton sleeve antenna (
see October 2011 QST) ... I built one of these recently and later added
2 more bands one antenna covering 20/15/12 and 10 ..simple to put up

21237. Re: [ham-antennas] 500' feed lines , Part 2

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-13 04:47:26 UTC
From: Artekmedia
Topic: 21211 Message: 21237

Point is..... the optimum location for the antenna farm is 500' from the shack .... looking for the most cost effective solution to get a feed line out there that is not effectively a 500' long cantenna . wire line looks like the best solution from a loss perspective but the impedance sucks when it comes to matching the tribander at the far end and the TL922 on this end....ergo matching transformers at each end ... need broadband transformers for 160 through 10 I work all of them equally. If I could afford it I would run 2" hard line out there and be done with it.

The issue is not about power, the cost of winding a 2KW balun is only pennies more than a 200w balun so that is not the quandry. The issue with the baluns is a truly broad band solution. Everything I have read so far says it is much easier to wind a 4:1 balun that is flat from 1Mhz to 50 MHz than it is to wind a 16:1 balun that is flat over the same range.

Another poster suggested forget about trying to match the 50 ohm line to to the open wire exactly and just use the 4:1 balun at each end and take the mismatch to the 600ohm line presumably from the perspective that any mismatch on a open wire line is of no consequence from a loss perspective . Now I have never seen anyone actually report on how well that worked out but lets do the math .

1) 4:1 balun steps the 50 ohm load at the far end up to 200 ohms

2) Let say for the sake of argument that we have a 600ohm open wire feed line and it is exactly 1/4 wave long or a multiple there of ......this is by the way the worst case

3) Using the 1/4 wave line impedance transformation equation Zin=(Zo x Zo) / Zload..gives an impedance of (600 x 600) /200 = 1800 ohms at the other end

4) Now the 4:1 balun at the transmitter end of the line steps the 1800 ohms down to 450 ohms presenting the TL922 with a 9:1 mismatch which high power amps REALLY DO NOT LIKE resulting in all kinds of "interesting and exciting" behaviors

5) Depending on the actual line length other interesting impedance's result as we move around the smith chart until we get magically to lines which are EXACTLY 1/2 wave or a multiple there off. In that rare case the 200 ohm impedance at the load arrives at the transmitter end as exactly 200 ohms. and is 4:1 stepped back down to 50 ohms. Having a rubber feed line that is always EXACTLY a 1/2 wave long at all frequencies is not practical and that is in one perspective what antenna tuners do .

6) In case you missed it in the original post using antenna tuners is
NOT an option in this case but it would likely solve the mismatch
impedance transformation problem. . If your into using antenna tuners
then the impedance mismatch as a result of the open wire line mismatch
could be solved. Unlike baluns 2kw antenna tuners are significantly more
expensive than 200W tuners. Also depending on the configuration and the
impedance mismatch the losses in the tuner can be significant,
certainly more than a few tenths of a db lost in a well designed balun.

Ok, im eventually going to be doing the same thing .... cept slightly over 1000'.

Im not sure of cost ... but why not use power splitters .. and simpler 1:9 transformers ...

Like 4 250w SS PA's ... without the transistors.

It will handle the power and broadband ...

21240. RE: [ham-antennas] 500' feed lines , Part 2

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-13 05:26:31 UTC
From: Tom Mitchell VE7TOM
Topic: 21211 Message: 21240

I do this with about 450 feet of feed line and have about 1.2 to 1.4 DB loss on 20 meters from the coax in the back of the transceiver through the amp to the output of the remote antenna switch box. I have measured two different ways - Bird watt meter and dummy load and antenna analyzer. They agree with each other.

I am using about 20 feet of coax from inside the house to a DXE 5KW balun to 450 ohm ribbon line. Then run 450 feet up the hill using electric fence 6 or 8 inch insulators on tops of garden posts and trees trucks. At the top end I have a relay box to switch the 450 ohm ribbon line to several other 450 ohm antennas as well as another DXE balun to get back to 50 ohms. That balun goes to a remote coaxial antenna switch for my 50 ohm antennas.

Works well. There are several sizes of wire used in 450 ohm ribbon wire. If QRO then get the bigger wire size. Helps lower resistive losses somewhat but also more copper so stronger in a wind storm.

Twist the ribbon wire every few feet. The goal is to cancel out any E field such as other noise sources the ribbon experiences. In theory it may work but the ribbon is probably not that well balanced anyways due to routing nearby other objects and ground and tree proximity.

No RF in the shack and the antennas are high on a hill with a 270 degree clear view. No household electrical noise picked up by the antennas either. However, my wife keeps turning on an electric fencer on the horse paddock near the antenna site and that tests the noise blankers in the radios. Fortunately, the fencer has an off switch for important contests and rare Dx.

Tom

Thanks !!! Exactly what I was looking for so by the time you get to 10 meters the loss is maybe 2 to 2.5 db?

Dave

On 12/12/2011 11:26 PM, Tom Mitchell VE7TOM wrote:
> I do this with about 450 feet of feed line and have about 1.2 to 1.4 DB loss on 20 meters from the coax in the back of the transceiver through the amp to the output of the remote antenna switch box. I have measured two different ways - Bird watt meter and dummy load and antenna analyzer. They agree with each other.
>
> I am using about 20 feet of coax from inside the house to a DXE 5KW balun to 450 ohm ribbon line. Then run 450 feet up the hill using electric fence 6 or 8 inch insulators on tops of garden posts and trees trucks. At the top end I have a relay box to switch the 450 ohm ribbon line to several other 450 ohm antennas as well as another DXE balun to get back to 50 ohms. That balun goes to a remote coaxial antenna switch for my 50 ohm antennas.
>
> Works well. There are several sizes of wire used in 450 ohm ribbon wire. If QRO then get the bigger wire size. Helps lower resistive losses somewhat but also more copper so stronger in a wind storm.
>
> Twist the ribbon wire every few feet. The goal is to cancel out any E field such as other noise sources the ribbon experiences. In theory it may work but the ribbon is probably not that well balanced anyways due to routing nearby other objects and ground and tree proximity.
>
> No RF in the shack and the antennas are high on a hill with a 270 degree clear view. No household electrical noise picked up by the antennas either.
> However, my wife keeps turning on an electric fencer on the horse paddock near the antenna site and that tests the noise blankers in the radios.
> Fortunately, the fencer has an off switch for important contests and rare Dx.

21243. RE: [ham-antennas] 500' feed lines , Part 2

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-13 06:11:58 UTC
From: MIKE DURKIN
Topic: 21211 Message: 21243

Ill start off with saying it sucks being limited to character count - but im using a DROIDX and cell for internet.
I would think that 4 runs of 450 open would have less loss than one with thick wire to handle the power.

I was thinking that using a QRO rated power spliter then 2 more of less rated power ... then step up with 4 1:9 balun/transformer - one for each run.

Hi Gloria use a HF flagpole design from the ARRL Antenna Compendium or try Ham Antenna Books from your local library.

My first antenna was a 14avq from Higain its a vertical for 10 thur 40 meters, works well on roof or ground. Allso a G5RV is a good start at very little cost if you have some trees to hang it.

If you have 70 feet between two high supports (or more), use enough RG-6 or RG-59 to get to 3
insulators and 64 feet of electrical wire (AWG 14 THHN or similar) to build a 40 meter dipole. Use
a pulley at one end and weight at knee level (1/2 of a concrete block would do), use some "Dacron"
cord 3/16" or a bit thicker. Don't cut the ends fold the excess (4-6') back.

Mike

OK now I understand your perspective

For the sake of argument lets say that our choices are either
1) 450 ohm line made from #18 solid wire for low power and assume a loss
at 30 MHz of .15db/100ft (ARRL Antenna book)
2) 450 ohm line using #14 stranded for high power. and assume a loss of
.12 dB/100ft (I am still trying to find the actual numbers for this stuff)
3) True open wire from made from #12
3) In both cases we will use your example of 1000' run
4) I will assume .1db of loss for each splitter and .2db loss for the
1:9 matching transformer

Example #1: Two #18 lines in parallel
1) The line loss is cut in half or .075dB/100' for a total of .75db for
the 1000' run
2) 2 power splitters loss .2db
3) 2 impedance matching losses of .4db total
4) total system loss of 1.35 db
5) Line cost @ $.297/ft = 2000 x.297 = $564
6) Assume we are winding our own splitters and baluns at $10 each four
of them = $40
7) Total system cost $604

Example #2: four #18 lines in parallel
1) The line loss is cut in half or .0375dB/100' for a total of .375db
for the 1000' run
2) power splitters losses .4db (splitter in series with splitter on
each end)
3) 2 impedance matching losses of .4db total
4) total system loss of 1.175 db
5) Line cost @ $.297/ft = 4000 x.297 = $1188
6) Assume we are winding our own splitters and baluns at $10 each 8 of
them = $80
7) Total system cost $1268 ....

Example #3 one #14 line
1) The Assumed line loss is .12dB/100' for a total of 1.2db for the
1000' run
2) no power splitters
3) 2 impedance matching losses of .4db total
4) total system loss of 1.6db
5) Line cost @ $.621/ft = 1000 x..621 = $621
6) Assume we are winding our own splitters and baluns at $10 each 2 of
them = $20

7) Total system cost $641

Example #4: true open wire line using number #12 wire
1) The Assumed line loss is .10 dB/100' for a total of 1db for the
1000' run
2) no power splitters
3) 2 impedance matching losses of .4db total
4) total system loss of 1.4db
5) Wire cost @ $.135/ft = 2000 x.135 = $270
6) Assume we are winding our own splitters and baluns at $10 each 2 of
them = $20
7) Total system cost $310
8) Ignores the cost of support poles and spreaders, very labor intensive
to install
9) Depending on the spreader investment "twisting: the line can be
problematic

Final Example #5 True open wire line using a 4 wire cage
1) The Assumed line loss is .05 dB/100' for a total of .5db for the
1000' run
2) no power splitters
3) 2 impedance matching losses of .4db total
4) total system loss of .9db
5) Wire cost @ $.135/ft = 4000 x.135 = $540
6) Assume we are winding our own splitters and baluns at $10 each 2 of
them = $20
7) Total system cost $310
8) Ignores the cost of support poles and spreaders, very labor intensive
to install
9) Because of the spreader geometry I perceive "twisting: the line to
be less of a problem

This compares to say something like LMR900 which has 3db Loss in 1000'
at 30 mhz for $7000
And LMR400 with a 7db loss at 30MHz/1000ft for $1000

21248. RE: [ham-antennas] what was your first HF antenna Or what would you recommend as a first HF antenna

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-13 14:51:27 UTC
From: Richard Schmuke
Topic: 21234 Message: 21248

My first antenna was a 40M dipole, used it on 40 & 15. Bands were not open back then so I made a 80M loaded vertical, did not have room for 80 dipole. A year into ham radio I bought a Mosley vertical , 10 thru 40, it still works fine 30 years later. Mosley makes a fine product. They have always been a local product also.

Today I would look at dipoles on the higher bands 20, 15 and 10.

Rich, Kd0zz

Subject: Re: [ham-antennas] what was your first HF antenna Or what would you recommend as a first HF antenna

Stephen KJ6DDF Bennett wrote:

> I have a Kenwood TS-590S it's my first HF rig and I wondering what would be a good first antenna

If you have 70 feet between two high supports (or more), use enough RG-6 or RG-59 to get to 3
insulators and 64 feet of electrical wire (AWG 14 THHN or similar) to build a 40 meter dipole. Use
a pulley at one end and weight at knee level (1/2 of a concrete block would do), use some "Dacron"
cord 3/16" or a bit thicker. Don't cut the ends fold the excess (4-6') back.

If you have room for a 40m dipole, you have room for an 80m dipole, just bend the ends wherever there is room to put them.

You can get the SO-239 studs at Radio Shack or at any CB shop at the big truck stops on the interstate. I saw some really heavy duty units at Loves Truck Stop on I-75 a couple of weeks ago.

The SO-239 adapter does have a 3/8 X 24 male stud that screws into a 3/8 X 24 female hex nut which is about one inch long and is long enough to leave threads to accept a 3/8 X 24 stud on the base of the antenna. A nylon washer is included to insulate the antenna side from the mount.

Subject: RE: [ham-antennas] Re: Open stub J-pole

I have the SO-239 and 3/8-24 adaptor also, the factory drawing looks like it has a male stud not a 3/8-24 female, I was looking for a SO-239 with a large male stud as a integral part.

SS steel wire would have a difference with a 80M antenna but remember almost all 3 to 4ft whips are 17-7 stainless steel

Rich , Kd0zz

Subject: [ham-antennas] Re: Open stub J-pole

I found mine at a truck stop and also have seen them at rad shack. I want to make another OSJ using 3/8" stainless steel tubing. Does anyone know if it would perform the same? Or is aluminum still the best choice?

Perhaps the article you were trying to remember/find was in the October 1980 issue of Ham Radio Magazine. It covers the subject, including 4 wire lines, in quite a bit of detail.

Actually a very good point since all the lines should be the same
length essentially paralleling the 4 lines should work. The combined
impedance would be on the order of 100 ohms for 4 lines and then a 2:1
balun (4: 1 in the case of the 2 parallel lines) makes the case for
only having 2 lines more compelling even for high power. the added cost
of he two extra lines only buys you an extra .35db of signal

In another application I created a 25 ohm 1/4 wave stub by paralleling
two 1/4 wave sections of 50 ohm coax once

My first ham antenna was my last swl antenna. 135' end fed. The antenna was wound on a toroid then to a ground rod. Coax from the rig terminated in windings on the toroid. Antenna and coax DC isolated, sort of a (fairly) broadband inverted L, good from 80m up at least through 20m without a tuner. Later learned a little more and made an 80m OCF dipole with a homebrew balun. Homebrewing swl antennas just naturally led to homebrew ham antennas.

Have fun on the air!

From: Don Sanders
Topic: 21234 Message: 21262

As several have said, dipoles are the best starting and for many
permanently.
My first was a windom, NOT. Hard to load and RF in the shack. Then I put up
a 40/80 meter dipole one feed line RG8. The 40 ran NW to SE and the 80 SW
to NE.
I worked the world on 80, 40, and 15 with my DX35 and SX99. Today I run
parallel dipoles for 80 thru 17 with coax feed, RG8X. With the LDG AT100
PRO
I can operate all bands. I have a MOXON on 10 and 12 meters.
I dont believe you can beat resonant half wave dipoles for general
operation.

If you dont want to bother with multiple dipoles, I recommend an 88 foot
doublet
with open wire or 450 ohm feed line. You will need a tuner but you will
have all
band 80 thru 10 operation
.Yes, I have one up at 90 degrees to the parallel dipoles for the second
rig.
That is over 60 years operation with dipoles.

You have not had any "luck trying to get it to work on 15 meters" in what way? Can't hear anything? Can't load it? Nobody answers you?

A 40m dipole WILL work on 15, I did that back in my novice days and I've done it since then. Heck, I even use my 40m dipole on 30m, and worked VK with it.

That's so simple it should of ocurred to me .... 450/2=225ohm.... but 3 runs of 600ohm line ... hummg .... wonder how much separation is needed from each run.

I worked my Elmer in 15 meters weekly, one day he used his 40 meter dipole (his emergency 15
meter antenna) instead of his tri-band "L" antenna, few could hear him, all that could said he was
weak as water. I think it works, but it is quite inefficient.

I have seen one reference on one distributors web (DXE ?) site that
says the 450 ohm window line is really closer to 400ohm. I think when I
get to that point I will actually measure it

From: Frank Kirschner
Topic: 21261 Message: 21267

If it is cut to resonate at 7.150 MHz, then it will resonate at 21.450, which may be a bit too high. I cut my last 40 meter dipole for around 7.070 (I work mostly CW and digital), and it worked well on 15, resonating around 21.210, but usable over the entire band.

A 40 meter half wave dipole should work fine as a 15 meter one and a half wave doublet.

not able to load it . SWR remains above 5:1. dipole is approx 34 ft per side . the centre frequency on 40 is 7.2375 and the SWR there is 1.4:1 . it covers the entire general segment without using the internal tuner on the ft 950 and the tuner will not match it on 15 . don't have any problem hearing anyone on the band. maybe that is the problem . 40 works well and I don't want to mess it up trying to get 15 working . I only have 3 trees and the hurricane fence to tie the ends to and I already have 6 wires in the air , 10 , 20 and 40 metres . the balun is a bencher ZA1A.

You are absolutly right, Ken. Mine was cut for 40 meter CW (7.100 mHz).
Three times that is 21.300 right in the middle of 15 meters. Have done this
for ages with my 80/40 ARRL Trap Dipole.

Subject: [ham-antennas] Re: what was your first HF antenna Or what would you recommend as a first HF antenna

My first ham antenna was my last swl antenna. 135' end fed. The antenna was wound on a toroid then to a ground rod. Coax from the rig terminated in windings on the toroid. Antenna and coax DC isolated, sort of a (fairly) broadband inverted L, good from 80m up at least through 20m without a tuner. Later learned a little more and made an 80m OCF dipole with a homebrew balun. Homebrewing swl antennas just naturally led to homebrew ham antennas.

Have fun on the air!

21272. Re: [ham-antennas] Unwanted A4 resonance shift

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-13 19:36:09 UTC
From: Nelson Wittstock
Topic: 20923 Message: 21272

Today I solved my problem. After replacing my coax as it had been a suspect in my situation with an erratic SWR, the problem was still present. The best SWR in all four bands was higher in frequency than the upper band edge. The next possible cause was the traps. I had previously cleaned them out and put screening over the vent holes so I felt that this solution was still not all that likely but I didn't see what else it could be. Today I replaced both driven element ten meter traps and tha antenna has excellent SWR's right where they should be on all the bands. The end cap had cracked open on one of the traps but there was no sign of insect activity. What I did find was that one of the screws inside that secured an end of the coil was loose enough to allow the attachment point to wiggle. It had the factory applied sealant but was slightly loose anyway. Apparently the connection to the coil was intermittent enough to mess up the whole works. This hobby can certainly keep the analytical brain juices flowing.

How about the the 600ohm line but with 2 baluns at each end one for low and one for high that are relay switched in? Now I know it is another cable and yes it cannot be too close to feed but best of both worlds? Conversly an old touring caravan close to antenna as the shack.

My first transmitter had the mic and antenna connections the same physical set-up, which would have made that mistake easy to make. Nowadays, with the advice of Murphy, the connectors are impossible to reverse.

My first antenna was a HyGain dipole. I strung it between the tree in our yard and the one in the neighbor's yard. It worked OK.

With a TS-590S as a first rig, I'd think about a pretty good quality antenna. I'm currently using a 102-ft doublet fed with 450 ohm window line, up about 70 feet, which works OK. I'm trying to get a permit to put up a tower and a three element quad.

Have fun.

21276. RE: [ham-antennas] 500' feed lines , Part 2

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-13 20:07:54 UTC
From: Tom Mitchell VE7TOM
Topic: 21211 Message: 21276

Dave,

Have not measured on 10 but 2 to 2.5 DB is a realistic expectation as the balun and connector losses probably increase slightly in addition to my short run coax from the house to the first balun. Much better than coax or large diameter hardline for these sorts or runs. The only down side is ribbon or open wire feeder takes a bit more work and care to install when running horizontally than coax.

Tom

Tom

Thanks !!! Exactly what I was looking for so by the time you get to 10 meters the loss is maybe 2 to 2.5 db?

More information on the size of your property, available trees or supports would go a long way in having us help you with your first antenna.

However, if you have room for a dipole with legs that are 65 feet per side then make a doublet.

Use 450 ohm ladder line to feed it. If you can keep the ladder line off the ground and connect it to a good 4:1 current balun just outside your shack window, then a short run of coax to the tuner you will have an antenna that will cover every band from 80 meters right up to 10 meters.

The internal tuner may or may tune some of the bands so you would be better off with a good external tuner. You could also run the ladder line right to the tuner if it has a 4:1 balun built it. But if I was going that route I would prefer to keep the ladder line outside of the shack.

You can also build fan dipoles. One coax feed line connected to the feed point then dipoles for different bands connected at the feed point. You need to be able to spread the legs of the dipoles apart so they do not interact with each other.

The beauty of the fan dipole is the fact you can trim the legs of it for each band and get away without running an external tuner. The tuner in the radio can handle any mismatch you may have.

Ground mounted verticals are also a good way to go. However you need to lay down lots of radials so the antenna works properly. Hustler 4BTV gives you 40-20-15 and 10 meters. You can add 17 and 12 meters too it by adding wires suspended out from the vertical and connecting them to the feed point of the vertical. But remember you must put down at least 32 radials so the antenna works properly.

If you can afford a tower, rotor and multi band beam then go that route. You can also suspend wire antennas off the tower by using a support arm at the top of the tower. You can then cover 80-60-40-17 meters that way.

So many options, that is why it is important for us to know the lay out of your property.

Topic: 21261 Message: 21278

Let's start with a little basic antenna, if you build a 40M dipole and adjust the angle and height you can get a 1:1 SWR so the radio would be seeing about a 50ohm load. Let not get too technical and try to keep this simple for now. When you try to use a 40M antenna on 15M it becomes a 100 ohm antenna, 3/4wl each side about so the best would be about 2:1 SWR. What are your readings on 15M? I use two different antennas on 15 that work fine as multi wavelength, a 80m loop and a 135ft dipole.

What is your problem, you can't hear, bad SWR or rig wont tune it?

Rich, Kd0zz

Subject: [ham-antennas] using 40 metre dipole on 15 metres

since 15 metres is a harmonic of 40 and my 40 metre dipole is cut for low swr at the centre frequency of the general band segment , approx. 34 ft/side . I have not had any luck trying to get it to work on 15 metres . what do I need to do to gat it to work ?

First HF antennas were 80M Inverted-V and Hygain 14AVQ mounted on the roof.

Both worked Great!

My two peneth

What is your QTH like? Trees/supports available? lots of room? covenants? if you have room a good starting point is a dipole for the lowest frequency band you want and then the odd harmonics will be available as others have said. I have G5RV and OCFD and except 15m the OCFD wins but have had RF in shack. Your radio got a good review in "Radcom" a few months ago by the way.

I also have a half wave vertical (ala: AA5TB http://aa5tb.com/efha.html) and it is tuned for 15m but my little LDG-Z11 pro11 tunes it from 20-10m and I regularly get accross the Atlantic on it, last couple of weeks just after the Sun has set and 10m fades on my OCFD the half wave vertical gives me another 30mins into LU/PY etc.

I would say though if using outboard tuner then you must turn off the one on the radio or you will have expensive brick. This has been a topic on the FT-450 group (my radio) and the internal components of on-board tuner can get all sorts of high voltages when there are 2 tuners in line.

So back to original question best first antenna is the one that you can make that gets you out. I would consider the following in order:

Wire Antennas

Dipole
Fan Dipole
OCFD

Vertical

Quarter Wave with ground plane/radials (even 2 will work, more is better but you will get out)
Half wave without ground plane

Hope to catch you on the bands

Jon

21281. Re: using 40 meter dipole on 15 meters

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-13 20:45:21 UTC
From: VE3FMC
Topic: 21261 Message: 21281

The problem you are having is due to the fact that the internal tuner on the FT-950 will struggle to tune a 5:1 SWR. Well known fact that most internal tuners will not tune much higher than a 3:1 SWR.

Now in my case my 40 meter dipole can be tuned by the internal tuner on my FT-950. The external SWR meter shows an SWR of between 3:1 and 4:1 on my 40 meter dipole when I am on 15 meters.

My 40 meter dipole SWR curve goes from 1:5:1 at 7.000 down to 1:1 from 7.125 to 7.185 then rises back up to 1:5:1 at 7.299.

So my advice would be to try an external tuner and you will be able to tune your 40 meter dipole on 15 meters. I currently have no antenna for 15 so I use the 40 meter dipole and make contacts with it.

I also have an Antron 99 vertical mounted at 24 feet. When comparing signals between it and the 40 meter dipole the signal strengths vary. Some stations are stronger on the dipole, some are stronger on the Antron. The SWR is under 3:1 on the Antron, but that does not mean the antenna is an efficient radiator on 15 meters!

Another thing you can do is simply add the legs of a 15 meter dipole to the feed point of your 40 meter dipole, trim them to resonance and call it a day. If you do not have an external tuner then that may be the route you have to take.

A SWR of 1.4 on 40 and 5:1 on 15 does not compute in this old mind. The simplest thing I know of is to make your 20 or 40 into a 2 band fan dipole by adding a extra wire. I made a 5 band one so a 2 band would be simple.

I just worked ZK2V on the island of Niue with my 40 meter dipole on 15 meters. Mind you I had to turn the amp on, 500 watts to make the contact. But then again my 40 meter dipole has an apex at 28 feet so it is not what you would call a DX machine :)

not able to load it . SWR remains above 5:1. dipole is approx 34 ft per side
. the centre frequency on 40 is 7.2375 and the SWR there is 1.4:1 . it covers the entire general segment without using the internal tuner on the ft
950 and the tuner will not match it on 15 . don't have any problem hearing anyone on the band. maybe that is the problem . 40 works well and I don't want to mess it up trying to get 15 working . I only have 3 trees and the hurricane fence to tie the ends to and I already have 6 wires in the air , 10 , 20 and 40 metres . the balun is a bencher ZA1A.

I have come to the conclusion that I will have to add another wire to it . I already have 6 wires on it for 10 , 20 and 40 metres and am running out of places to tie the ends to . still want to add 15 , 17 and maybe 12 metres to it . just doing 1 band at a time . I do not have enough real estate for 135' of wire , also do not have space for 75 metres so will have to do something else with it .

Make the antenna a bit longer that it will resonate on 7.050 or 7.075
(something in that range) ... that should lower the swr on 15 and should
still be tuneable on the whole 40m band

Have you considered the ZS6BKW antenna? Most bands do not require a tuner, and is is shorter than a G5RV. Simple to construct, although I recommend using a voltage balun(also very easy to construct).

You can add the other dipoles below the 40m dipole ... no need to have all wires in different directions ... just add some spreaders to the bigger dipole were the ends of the shorter dipole will be ...
40 should work well on 15!! So only 12 and 17 need to be added ...
And you also can add 80m with bending the ends back ... or to a different support ...
The most radiation comes from the centre of the dipole so you can zig-zag the ends without much trouble

Topic: 21261 Message: 21289

Hi Fred,

The problem is the 40 metre frequency. Do the Math. 7.2375 Mhz X 3 = 21.7125 Mhz. Resonant Out of Band!!
You are trying to load it around 21.200 I assume. No wonder the SWR is very high.

As suggested, run a 15 metre dipole in parallel with the 40 metre one on the same feed line and tune to where you require it.
That will fix the problem - or retune the 40 metre to around 7.100. (7.1 X 3 = 21.300 Mhz).

73

My 1st antenna was a 80m OCF fed with a balun and 50 ohm coax to a FT-817. My 1st contact was to Venezuela PSK31 5w. The antenna was up 30'. After that I received a manual tuner that had a bad solder point (did not know this until after trying SSB). Once I fixed it I was off to the contacts.

The antenna I have up now is a fan dipole cut for 80 fed with 100' of 450 ladder line into the shack where it meets a 4:1 balun and 3' of 50 ohm coax.

In both cases the balun was homebrewed by KD9DVY.

UH, duh, I wish I did have numbers on it. I can tell you the first time I made it that it only worked well on 75M the other bands required additional wire, about a foot on 40 down to 6" on ten. I ran it between a couple of poles about 5 ft off the ground and trimmed it to a dip at the frequency's I wanted to operate then hoisted it up and all was fine. If you try one and have the wires spaced close like mine there will be interaction between the bands so trim the lowest frequency first and work your way up. The farther apart the wires are the less interaction, on mine as you can see there were about a little under 2 inches. Spacers were home made from a section of PVC conduit split into 4 sections and the drill slip fit for the wire used. It has been replaced with a much better antenna yet it is still in use at KC0ZIU's place. It was a good antenna and required one pulley at the center for a quick change.

The windowline is more to 400 ohms than to 450
As far as I know the different window lines are between 360 and 390 ohms ...
So 2 of them and a 1:4 and you are well matched ...
And if you use a halfwave length (or better say multiple of that) then it should work very broadband and with low loss
Dg9bfc
Sigi
Ps ... open wire can easy be twisted ... use a t bar on-top of every second post ... start vertical (lower and upper insulator on a fence post)
Insulators on next are left and right ... and so on ... and some spreaders between the posts to hold the distance

From: Don Sanders
Topic: 21234 Message: 21293

Another option for the vertical ground instead of radials is two runs of 30 to 40 feet long heavy chicken wire about 1 meter wide laid on the ground and crossing in the middle. Mount the vertical at the center of the cross. Connect the chicken wire together and to the coax shield. Several serious DXers use this method.

From: Larry Tooley
Topic: 21261 Message: 21294

Great advice. The lengths can be configured now. And yes that is the best way to tune it. Have the old ARRL GDO in the outbuilding I can use. Better turn it on and test it first. Maybe recap it. I do feel that antenna is the best. All band and matched to the feedline and transmitter.

Subject: RE: [ham-antennas] Re: using 40 meter dipole on 15 meters

UH, duh, I wish I did have numbers on it. I can tell you the first time I made it that it only worked well on 75M the other bands required additional
wire, about a foot on 40 down to 6" on ten. I ran it between a couple of poles about 5 ft off the ground and trimmed it to a dip at the frequency's I
wanted to operate then hoisted it up and all was fine. If you try one and have the wires spaced close like mine there will be interaction between the
bands so trim the lowest frequency first and work your way up. The farther apart the wires are the less interaction, on mine as you can see there were
about a little under 2 inches. Spacers were home made from a section of PVC
conduit split into 4 sections and the drill slip fit for the wire used. It has been replaced with a much better antenna yet it is still in use at KC0ZIU's place. It was a good antenna and required one pulley at the center
for a quick change.

A SWR of 1.4 on 40 and 5:1 on 15 does not compute in this old mind. The simplest thing I know of is to make your 20 or 40 into a 2 band fan dipole by adding a extra wire. I made a 5 band one so a 2 band would be simple.

not able to load it . SWR remains above 5:1. dipole is approx 34 ft per
side
. the centre frequency on 40 is 7.2375 and the SWR there is 1.4:1 . it
covers the entire general segment without using the internal tuner on the
ft
950 and the tuner will not match it on 15 . don't have any problem hearing
anyone on the band. maybe that is the problem . 40 works well and I don't
want to mess it up trying to get 15 working . I only have 3 trees and the
hurricane fence to tie the ends to and I already have 6 wires in the air ,
10 , 20 and 40 metres . the balun is a bencher ZA1A.

If you want to do math it is even worse than the numbers you came up with. The basic dipole measurement is 234/F MHz per side but when you are talking about a 3/4wl dipole or 15 on a forty the first 1/2wl of the 3/4wl you don't have a end effect so the number for that section is 495/ F MHz not the normal 468 so it is even a little farther off.

A fan would solve the problem.

Rich, Kd0zz

Subject: Re: [ham-antennas] Re: using 40 meter dipole on 15 meters

Hi Fred,

The problem is the 40 metre frequency. Do the Math. 7.2375 Mhz X 3 = 21.7125 Mhz. Resonant Out of Band!!
You are trying to load it around 21.200 I assume. No wonder the SWR is very high.

As suggested, run a 15 metre dipole in parallel with the 40 metre one on the

same feed line and tune to where you require it.
That will fix the problem - or retune the 40 metre to around 7.100. (7.1 X 3 = 21.300 Mhz).

A good thought Jon !

Since I do all my own balun work it would be definitely be cheaper than building a 4 wire line that I could match with a 4:1

Building an optimum 12:1 for 1 to 10Mhz and then another one for 14 to 28 is certainly much less of a challenge! The 600 ohm line is easy enough to DC isolate and use as the control line for the far relays that switch the two baluns.

Using my earlier cost analysis then for a 500' 2 wire system , $140 worth of wire and $40 for baluns would get me a feed system with .9dB loss at 30 MHz maybe less if the balun designs are really good.

It is simple to go to Lowe’s or Home Depot and next to the rope you will find 3 different sizes of plastic pulleys, for a couple buck each you can support your dipole on a pulley and it will be easy to raise, lower and adjust. You can always leave it a little long then check and trim. That the way us’ins do it out in the country. A friend of mine, W0SZV has his 1200ft loop supported with theses pulleys so they will hold up.

> already have 6 wires up .

Fan dipoles are great for two or three bands. When you start getting into 5,6,7 bands, the interactions get more complex. Prune one and it affects two others, etc.

Also, IIRC, because of "end effects" resonance is not exactly 3x the fundamental frequency.

Above all, do not confuse "resonance" with low SWR, They are unrelated! A 1:1 SWR does not mean the antenna is at resonance and "resonance" does not assure a low SWR.

Resonance is overrated, IMO.

If you want a single antenna for a half dozen different bands, a 100' long dipole fed with ladder line or open wire to a balun and tuner is a much better way to go IMO.

Ken WA8JXM

I agree with Ken about a large dipole, during the 10meter contest over the weekend I used a 135 dipole feed with ladder line and a loop. It is broadside N/S but on 10M it is 8 times the length of a 1/2wl dipole and has great lobes off the ends into Europe and the far east. The signal strength was several S units better than my loop by using the ends of the dipole. In mid day working the north and south America's the loop was about the same.

Subject: Re: [ham-antennas] 500' feed lines , Part 2

A good thought Jon !

Since I do all my own balun work it would be definitely be cheaper than

building a 4 wire line that I could match with a 4:1

Building an optimum 12:1 for 1 to 10Mhz and then another one for 14 to

28 is certainly much less of a challenge! The 600 ohm line is easy

enough to DC isolate and use as the control line for the far relays that

switch the two baluns.

Using my earlier cost analysis then for a 500' 2 wire system , $140

worth of wire and $40 for baluns would get me a feed system with .9dB

loss at 30 MHz maybe less if the balun designs are really good.

Dave

I'm glad VE3FMC mentioned the Antron A99 working 15 meters. Yesterday I had a long QSO with VE5CDO on 15 meters and he was using an A99. I was using a Hy Gain AV 640. He was peaking S9+10 in South Texas. Since all antennas are compromises, the A99 is another that works for just a few bucks. I have one and have worked 10 through 20 meters on it with an LDG Z100 autotuner.

Hi Richard

depending on depth of Anodising the corrosion protection may be limited. I seem to remember Sigi posting about using Aluminium welding wire a while back. I know Copper is going up but I just buy either enamelled Copper wire by 1/2Kg (I live near Rapid Electronics) or use multi-strand flexible with sheath and use that.

I know that both of these not being Cold drawn are subject to stretching but that is what my tuner is for. I know Rapid and I am sure other electronic shops have a marked down bin. I got about 500ft of multi-strand for a couple of pounds as the reel had been damaged and it was in a great big knot. Hour later I had it all coiled up and ready to use. The Ariel doesn't care that it was in a knot before use.

You can't solder to aluminum, of course, so then you depend on a mechanical connection only with something which may cold flow and/or corrode.

I don't know that copper is all that excessively priced. You can get 500# of #14 insulated THHN for $50 or #12 for 80# at Lowes. Likewise you can get copper clad wire from several ham suppliers at quite reasonable prices. Copper antenna wire is cheap compared to the coax to feed it.

I don't see the price of decent antenna wire being significant.

Now if you are talking about putting in 5000' of 160m radials, well then that's a different story.

Corrosion is not much of a problem with anodised Al, and I always use
clamp/crimp connections. Cu prices are much lower in the US, by the prices you
quoted.

Odd, copper doesn't rust! It does form a thin layer of copper oxide turning it green but should be able to lie out in the elements for hundreds of years. I myself don't like insulated wire because the insulation will decay long before the copper does.

We tried welding wire on a fieldday ... but only once ... cause we found out that is "bulls..." ... it is toooo hard so breaks very easy if you are not careful while installation
One "kink" and the wire is broken ... so welding wire is no good

What we tried then on next fieldday (and what I still use) is aluminium fence wire ...
Very light, does only corrode on surface (like any other antenna made from aluminium) ... does not stretch much and so little sag in center

As I joke I tell that the wire bends upwards if the sun heats the ground under it :-)

1.6, 2 and 2.5mm is what I have seen
And a friend from me made a really big antenna with 7 of the 1.6mm wires ... slightly twisted

Dg9bfc
Sigi

Ps 200 or 300 feet on one leg??? No problem with that wire!!

I’m sure not going to complain about the Antron 99 either. Mind you, my A-99 is on a 30 ft. push up mast running and a 1.5:1 and less match on 10 meters. About a month ago I talked to Japan and a couple of other countries with no problem.

Sorry getting , sent a blank reply.

Fine on the comments Sigi & Jon.
I'll ring a local stockholder and get prices.
One end of the wire antennas is hanging off the stub mast, see pic on qrz.com.
I don't want to get any bending on the stubmast, hence the need for low weight, but strength.

Oh well bed time before I make more mistakes.

what type material should the spreaders be and what end spacing between the wires ? La Grange does not have anything except a combination lumberyard and hardware store/feed store and a small walmart . no places to get anything except basic supplies .

Sigi,
*
*
*Aluminum wire! Not more than 40 minutes ago I finished stringing a 40m
end-feed made from wire cannibalized from old extension cords. They were
free, so . . . But it was a damn chore to extract the wire. Had I know
about using aluminum wire three hours ago I would have run down to Home
Depot and picked up a 250ft roll of 17awg fence wire. Their web site
indicates only $5.45 for the roll. Here's a shortened link:*
*
*
http://bit.ly/tE40DU
*
*
Many thanks (for future antennas).

I've been trying to follow this but the turns and twists are giving me a neck ache.
As far as I know one run of 600 Ohm transmission line made with AWG 14 will handle way more than
American full power any mode so why are we discussing running parallel runs?
The higher the impedance the lower the loss, (and the lower the RF current) so if we are calculating reduced losses why include 400/450 Ohms in the possibilities?

Hardware stores usually sell plastic water pipe made of PVC (PolyVinyl Chloride) that is what is
what I would use. (get white, the PVC cleaner will remove the imprinting from the pipe)
Get 3/4" with the thick wall.

I agree; Fire inspectors often use copper line to determine if electrical wiring may have been a contributor. It does not melt in a fire, and can be traced. The oxidation does occur, but you will find the fine plasti coating cracking off before it even reaches the insulation, and then the insulation finally giving way. I have had the same set of 14ga strand wire buried for my vertical for some 10 years and can still see the color of the insulation when it surfaces to the antenna mount.

Odd, copper doesn't rust! It does form a thin layer of copper oxide turning it green but should be able to lie out in the elements for hundreds of years. I myself don't like insulated wire because the insulation will decay long before the copper does.

Any place like the lumber yard should have some grey PVC conduit, that is what I used for spacers. I took the PVC and split it with a scroll saw into fourths.

End spacing can be whatever your heart desirers. 6☐ plus or minus 4☐ would be fine. I put spacers every 2ft because I had 5 wires and if I did not have then the wind would whip them into a birds nest. With just a 15m added to your forty you might get by with just one at the end. The straight section of a plastic coat hanger cut off and a hole in each end will work, anything light weight and non conductive. I have seen drawings of just a 3ft length of fishing line and a fishing sinker to hold the 15M section down. Your 40m becomes the main support, the 15 just hangs there.

> For a year, I used a 40m dipole with open wire feeder, cut for SSB; could never get it to a reasonable swr on 15m. Always astounded me... usually the Johnson Matchbox would load anything! Went to a trapped vertical... never looked back!

The Johnson Matchboxes have limited matching range compared to other tuners, but I still find that strange. Probably a function of the feedline length?

That's right!!

Acid core solder and freshly cleaned aluminium solders for me.
I scrub off all the acid with a stiff brush, soap and water when done and have had no troubles as time goes by. As far as using alum electric fence wire, being in a dry environment (not near any ocean here) it develops a light corrosion layer rapidly, then no more...after 2 years now. There are ways to deal with it being soft mechanically. Can buy it in 1/4 and 1/2 mile long spools at my local feed store for a very reasonable price.

Do a search on qrz.com for kf4tap he is a home brewer. A few years ago he had the same problem finding crystal sockets so he started making them. He may be able to fix you up with what you need

I am building one of the Four States QRP kit and would like to put a connector into the board to the crystal as opposted to directly putting in the crystal. Where I obtain one of these I was at ACK and they were no help ? In addition where can I find extra crystals ?

Hi,

I started working with Buddistick Buddipole and both are good.

But this year add a Chameleon V1 and the results have been amazing.
lightweight, practical, 80m - 6m plus 2m / 70cm.

I have a Youtube video of the installation of the antenna :

http://www.youtube.com/watch?v=dMH1WN8xVSA&feature=youtube_gdata_player

Subject: Re: [ham-antennas] Unwanted A4 resonance shift

Today I solved my problem. After replacing my coax as it had been a suspect in my situation with an erratic SWR, the problem was still present. The best SWR in all four bands was higher in frequency than the upper band edge. The next possible cause was the traps. I had previously cleaned them out and put screening over the vent holes so I felt that this solution was still not all that likely but I didn't see what else it could be. Today I replaced both driven element ten meter traps and tha antenna has excellent SWR's right where they should be on all the bands. The end cap had cracked open on one of the traps but there was no sign of insect activity. What I did find was that one of the screws inside that secured an end of the coil was loose enough to allow the attachment point to wiggle. It had the factory applied sealant but was slightly loose anyway. Apparently the connection to the coil was intermittent enough to mess up the whole works. This hobby can certainly keep the analytical brain juices flowing.

I like my Chameleon V2L on a fiberlass pole with a ground wire running down - 3 support guys . takes about 5 min to setup !
I also sometimes use a wire vertical [homebrew] if trees are around- just take a few fender washers tied together, attached to a string , fling 'em up in a tree - pull the vertical up - lay out a couple of counterpoise wires and away you go ....

From: Steve ~ W9SWT
Topic: 21337 Message: 21337

Hello All,

This is my first post to this group:

I've nearly finished a portable 20m vertical 2 element antenna (broadside pattern) inspired by WA3ULH's (now W3DX) 1995 QST article.

Now that winter is at hand, I wonder how snow or wet ground will effect performance of the radials. They will be spread out on the surface… of the snow or wet ground.

Thanks,

Steve ~ W9SWT

Although there are many schemes that can make this work, the "Zep" and the "J" pole antenna are
your best bet. The dipole "end" has an impedance of about 10,000 Ohms so a matching network is
necessary. That is the job of the "stub" which can be coaxial.

VERY BIG GRIN *G*
Just ask (not only me but hey what is this group made for?!?) ...
Welding wire (aluminium or stainless) is bulls... cause toooo hard (breaks too easy) ... but al fence wire can you have in a few different diameters and in different quality (more or less hard)
Here in dl in 400m rolls for 25-30 euros ... so yesssss it is very cheap, light-weight ... and does last very long :-)
Good luck for your next antenna projects

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-16 16:33:54 UTC
From: Ralph
Topic: 20549 Message: 21341

You could try the end fed matchbox with 33' dipole attached (20-40 meter) then attach another 33' to it for (80-120 meter). Got it from http://www.earchi.org
I put mine on a tripod and a 20' fishing pole and works for HF. But it has better range from the beach.

21348. can I use multi-conductor wire cut to different lengths for radial or radiator?

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-16 19:50:02 UTC
From: Paul
Topic: 21348 Message: 21348

Will it work to take four conductor cable and connect one end in common, then cut each of the four conductors to appropriate length for the desired bands, stripping off the excess per conductor wire?

So it is sort of like a Fan - but with no spread.

As a side question, if that will work for a Radial, will it also work if I wanted to make a wire vertical and use the same scheme for multiple radiator lengths - again, like a fan but without the spread?

Thank you and 73,
Paul

PS: I'm thinking of using Radio shack four conductor cable - it maybe 24 gauage.

That's a freaking WMD dude! It not only gets your antenna up on field
day but also eliminates any competition ;-)

21350. AW: [ham-antennas] can I use multi-conductor wire cut to different lengths for radial or radiator?

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-16 20:12:31 UTC
From: siegfried.jackstien
Topic: 21348 Message: 21350

It will work BUT
The interaction will make it hard to find the right length for the cuts
On higher bands high voltage at the ends will probably break insulation to
other wire (of a lower band)

Even with a bit of distance you have interaction ... as closer you get as
harder to tune so a difficult and maybe lossy thing

The max PSI I sugest is 80 PSI and the volume of the air chamber is about 110 C.I.
At that pressure I once shot over the tree , across the street and onto the top of another tree in most cases 40 is all.you need to get the antenna up. Now if you are just shooting for fun I have seen an un-weighted tennis ball shot the length of 3 football fields (300 yards)

21352. Mounting TH3 JR Beam on Roof

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-16 21:50:49 UTC
From: Dave Wilson
Topic: 21352 Message: 21352

Hi All,
Am new to this group. I am about to put my TH3 JR beam on the peak of my roof (along the spine). I will only be able to mount it about 5 feet above the peak, so I assume a lot the gain from this antenna will be lost in the roof and the ground. Is it possible to put out a decent signal with this lack of height above the roof? My alternative is to put in on a hill on my property (about 30 feet higher than my roof location) on a short tower, but will have to run about 200 feet of RG8U to it. That is about a 2 DB loss over the roof location. Any help or comments re the better choice? The hill choice is more difficult and more expensive. Thanks. Dave. WA6TXU.

Steve

As long as your planning on a dozen or more radials the snow and wet
ground will likely have little affect

Even with as few as 4 you will likely not be able to "hear" the difference

Have fun
Dave

Ideally, we'd all love wide spaced 4-el monobanders at 100 ft. However, you can still expect good results with the roof installation. See the QRZ page of WZ0V -- he's done quite well with a similar set-up.

Unless the hill location puts the antenna up to 50-60 feet AGL or so, I don't think it would perform much better than the roof.

Try it and see...experimentation is what's it's all about!

21356. zero five 43' vertical-- modify height question..

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-17 15:47:56 UTC
From: anthony
Topic: 21356 Message: 21356

I have a zero five 43' vertical with 60 ground radials. I preforms bad on 80. It does very well for long haul contacts on 40. Im looking to make it my 40 meter ONLY antenna. I am wondering if by shortening it to make it a 33' vertical which will be a perfect match for 40 would it preform any better or just leave well enough alone? Any ideas or input would be apreciated. good dx.

tony k2vi

43' is way short for 80m. I would not expect great performance from it on 80. You actually need 65 to 150' (half of 5/8 wavelengths) for optimum performance of a vertical on 80.

OTOH, 43' is better on 40m than 33' would be.

And no, making it 33' would not make it "a perfect match on 40" (without some sort of matching network) because the the feed impedance of a 33' vertical on 40m is in the 30 ohm neighborhood, not 50 ohms. 43' is a better match on 40m than 33' would be.

Leave it at 43' on 40M if it is already matched there. NO advantage to shortening it other than a very slight improvement (high angle) in local shorth distance use.

Why do say it is a dog on 80? Tough band for DX even with a full sized vertical especially if your running barefoot. How long are the radials?

So I'm reconfiguring my HF station, and one of the alternatives I'm considering would have coax and ground wire leaving my transceiver and running basically right beside each other for 5 feet or so before branching off to their respective destinations. Bad idea? Thoughts?

Thanks very much.

Hi Michael

with Coax it should make no difference as RF is contained within the coax. That is the advantage of it. absolute rubbish if SWR is high but thats swings and roundabouts I suppose.

Actually Mike, you'd want both the coax and ground to be running to the same place, the spot where the coax enters your building. It is there, just outside that entrance point, where your first ground rod should be driven with a second one spaced at twice the rod's length away. That is also where your line power should make connection to that same ground (the green wire).

Will suggest that you Google 'PolyPhaser and read their white papers... a world of knowledge which may just save you a world of hurt someday.

Subject: [ham-antennas] Dumb coax/grounding question

So I'm reconfiguring my HF station, and one of the alternatives I'm considering would have coax and ground wire leaving my transceiver and running basically right beside each other for 5 feet or so before branching off to their respective destinations. Bad idea? Thoughts?

Thanks very much.

Sadly, this winds up being the problem so often... antenna lead-ins at one end of the house or building (if commercial), line power coming in at the other. Strike current flowing in either direction over the 110 volt wiring and through the equipment, depending on what was struck.

So, you want to have all of your equipment in a kind of bubble with only one inlet point... the "entrance panel" which is a kind of electronic window that all the services (phone line too) enter through or are at least connected to. That way the strike current flows AROUND your gear, not through it.

Now, to do that the antenna's shield, and the green wire grounds from all of your equipment should go to ground at that point where the antenna cable enters your home.

Again, pointing back to the PolyPhaser company, they make an extension cord with a metallic two gang outlet box at one end, the typical three prong 15 amp plug at the other. The metal box is mounted onto the entrance panel effectively grounding all your equipment. BTW, MFJ offers a few models of entrance panels... don't remember what they call them though. Basically it's a panel which fits into your window frame with feedthrough connections for you antenna cables. What they don't offer is the outlet box which would be attached to the panel and plugged into a nearby wall outlet. The box/extension cord you should be able make with stuff from Lowes Also, you'll want to install lightning arrestors at the panel. They clip off the spike on the coax's center conductor generated by either a direct or nearby lightning strike. That spike can and will render your receivers deaf.

That will protect your equipment, but not the dwelling. Unfortunately, should the power line be struck, a portion of the strike will travel though the house wiring seeking the best ground... your hamshack ground. Yea, the power company ground will dissipate a portion, but their grounds deteriorate over time. The way to minimize strike current flowing through the house is to provide an alternate path around the outside of the structure, one end connected to your grounding system, the other to the power co's ground. Install several more ground rods connected to that outside ground path. Did I mention that this gets spendy... real fast? For the dope on this method, Google 'halo ground', or grounding.

Some years back, I had to deal with a business that lost equipment twice to lightning (they were warned about the deficiencies in their system several times but it sometimes takes a smack in the back of the head to get the needed attention). We added three more spaced out ground rods at the tower's base and installed an entrance panel like I described above, complete with arrestors and that outlet box. I've not had to replace a blown radio since! And with an eighty foot plus tall tower and a twenty

foot tall low band antenna at the top they have taken subsequent strikes I've been told.

Again, the PolyPhaser site has an encyclopedia of knowledge on the effects of lightning and how to deal with it. From their research, they have literally written the book on the subject. Follow it and sleep well at night.

I take it your saying the whole house ground should be your second ground. My problem is the whole house ground is like 70’ away from where my radio shack is at. I live in a big house. There is a lot of concrete between me and the ground.

It sounds like you have beginnings of a grounding halo. Ground Halo's
are very common in the broadcast industry. They take a ground line from
ground point "A", passed a select group of equipment to be grounded, to
ground point "B", then run a ground line from Ground Point "B" back to
"A" passed more gear to be grounded.

Dont confuse your single point equipment ground with this halo ground mentioned.

Your RF equipment needs a single point ground to keep everything at the same potential. This is an important part of a shack setup to fight RF problems.

I learned a lot about this when fighting RF in my shack this fall.

Thanks Stan for the suggestion to read up on the Polyphaser site. There was stuff I did not know.

I have a second floor shack and do not have a proper enterance ground for lightening protection I have a good RF equipment ground but the more I read the more I am starting to understand the differences. I have been thinking about moving the shack to the basement to for lightening protection and other reasons. I can put the shack close to the power enterance and bond the ground system and add extra rods easily if I move the location and can keep the wire real short. Now I am convinced that this has to be done in the spring when I can move my dipole antennas.

Right now I a bit of time as there is not much lightening in Michigan in winter.

In any case I have some work to do.

Merry Christmas

Tony,

Glad to have helped. As for "they should not advertise it for a functional antenna on 80", well you have to read and understand the specs. EVERY antenna is a compromise. There just are absolutely no magic antennas that do it all. The more you understand about antennas, the more you will be able to analyze the advertising and specs and understand where the compromises are and decide if it is a reasonable compromise for you.

It sure beats some of the guys that are limited to an indoor antenna in their living room!

21379. v beam and dipole possible interaction

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-19 00:02:34 UTC
From: fly_ul
Topic: 21379 Message: 21379

I am building a set of v beams similar to that in March 2011 QST. The only difference is that my legs are 120 feet instead of 108 feet. I have the center height at 44 feet and the ends at 10 feet. I understand some people love v beams and some people hate v beams. I just like to build antenna and test them. I have a couple of questions?
1. Since the outside legs are 135 degrees apart could I feed it at 160 meters and use it as a dipole?
2. What would be the effect of adding an 80 meter dipole on the same tower at 30 feet? It would be lower by 14 feet at the center and dropping to 10 feet at the ends and it would offset from the outer most v beam elements by 22.5 degrees. I suspect there would be too many wires running in front of the dipole causing much interaction between the two antennas.
3. I just downloaded MMANA and was going to model this but it will take this old geezer a while to get this program figured out. There are some sample v beams but not a 4 element switchable. Does anyone have a similiar model I could use?

I hope this works as described in QST. We shall soon see. Hopefully during Christmas when the kids are home I can get them to put this up.

Thanks in advance for any answers

Actually, the station can stay on the second floor if that meets your needs, but the cables should come in at ground level, then up through the ceiling to your shack. Remember that the station power needs follow the path of the antenna cables from the entrance panel. Again, the station should be in an electronic capsule with a single entry.

Understand that if the system is struck, the whole shack, radio, computer, etc. will jump to some high level of voltage for a split instant, but since there is no current flowing from device to device on its way to ground, the equipment will not take notice.

Picture an airliner being struck, the bolt hits the nose and exits the tail but all within the fuselage might hear a loud bang, maybe, but the radios and instruments still work.

Thanks Dave,

Because it snowed just in time for the weekend, the ground was snowy and wet. I hadn't weather sealed the 2 verticals (for posible adjustments), so I didn't want to lay them on the ground to measure the 1/2 wave separation.

So I put up one and used it as a simple ground plane. It didn't budge the SWR meter (FT-857D) across the whole voice portion of the 20m band. Contacted a station in eastern France.

I live with antenna restrictions, but wire strung low to the roof doesn't draw attention. I'm thinking about building a loop at about 9 inches above the roof on PVC sections. It would follow the pitch of the roof peaking about 4 feet higher at the center then dropping back down the other side. Does this seem like it will function correctly or will the sloping plain be an issue? I would just try it but putting up all the supports and springs isn't fun.

Jim

The antenna will work. I would not plan on running any power more than 100 watts. Even barefoot you may find you have a lot of problems with TVI and the radio getting into your phones and stereo as this set up will likely couple into the wiring in the house. I have on occasion loaded the metal trim around the edge of roof and even made a contact or two that way on 160M. I am guessing as it is relatively low to the ground that this antenna will be good for short range more than DX.... but you will get out

Recently I made several QSO's (several of them DX) on 30M with nothing more than a 25' piece of hook up wire connected directly to the output of my TS950 and then out the window to a tree.

If you want to beat those HOA rules here is a neat trick that will work.

If you have a long rain gutter on your home you can put some Christmas lights up on the gutters using those little plastic clips that clip on the gutters then hold the light bulbs.

Now surely there are no laws against Christmas lights. So you then take the extension cord to your shack window. Cut the plug off and solder on a coax pigtail and run that to a good tuner.

Now you have an antenna! Try to keep the extension cord off the ground if possible.

That setup is just like having a loop, only it is close spaced. I have done this in the past with 50 feet of lights and another 25 feet of extension cord. So that is like having 150 feet of wire. It tuned very easily on 40 meters. I only ran 100 watts into it at the time. Would have been fun to run 300-400 watts into it to see if the lights flickered off and on with the SSB audio :)

Your idea of the loop suspended just above the roof will work too. If you can get it higher off the roof that would be better of course. Maybe you could use magnet wire suspended with small black supports.

Hey any antenna is better than no antenna.

73, Merry Christmas to all from Rick VE3FMC

And every few feet you have a resistor in the wire (the light bulb)
No good idea ...
There are better ways to get over hoa rules:
Flagpole as an example
with added tophat wire(s) good for the lowbands
without tophat good for 10-40
Or bird feeder hanging down from a tree (to protect the antenna or coax that is in the tree)
The small stand-offs and a thin wire would surely be nearly invisible
(the loop along the house)
And if somebody says something against that nearly not noticeable antenna tell that it is for emergency use (remember them on earthquakes and thunderstorms etc.) ... and as a "patriotic" nobody will be upset that you have a flagpole ...
As "non-patriotic" you can hiss a Ferrari flag and say you are a "micheal-schumacher-fan" :-) (or a "becks-flag" and say you love german beer hi hi)

The thing is not that you are not allowed to erect an antenna ... the problem is that the antenna has to be stealthy ...
And there are many many solutions for that

You will find a lot solutions if you look for stealthy antennas or antennas for a small garden (on4un low band dxing chapter 14 as an example)

So GET ON THE AIR :-)

21392. multiple OCFD

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-21 10:55:01 UTC
From: Richard
Topic: 21392 Message: 21392

Hi
Sitting here twiddling my thumbs waiting for some Aluminium fencing wire to arrive by post, I was wondering whether I maybe better off using a OCFD cut for 40mtrs, with a 4:1 balun and coaxial
feed.
Advantage, that any mismatch at resonance will be divided down as well, would there be any advantage
using a similar construction to a multiple CF dipole to get a better match on the higher bands ?

Why only cut for 40???
Ever heard of the centerloaded ocfd??
That gives you more bands and a better match
You can also add more bands with a fan-like ocfd (two different ones
paralleled at the balun)

Is it more of an issue with loops than say dipoles? My current antenna is a 40 meter OCFD and I do have problems from time to time with some devices (Especially motion lights and touch lamps), it seems to be frequency dependent. So far I've found bare #16 copper wire doesn't attract attention and I could fit a 40 meter loop all within the roof area.

Every situation is different and RFI in the house depends on the self resonance of the wiring in the house (a function of the house wring lengths). RF grounding sometimes helps and a separate RF ground close to your equipment is always a good idea and often helps. High power of course makes it worse. No easy way to predict how much coupling you will have , your just going to have to put it up and see what happens

Touch lamps are another beast all together ... I recall a situation I had years ago at a different QTH. I was running high power and a "stealth Inverted L" on 160M . Usually I was only on that band late at night around midnight local time catching the sunrise into Europe. The next door neighbor was not even aware I was a ham and one day he mentions to me he was wondering whether or not he had a ghost ! Seems the ghost would turn on the touch lamp at his bedside late at night. The light would go from dim to bright , to brighter and off again in rapid succession (around 15-25 wpm :-)) this would last for a few seconds to a minute or more and then would quit for a few minutes ..it was waking him up and driving him nuts. A simple ghost proofing technique of adding a ferrite to the power cord of the lamp discouraged the ghost from returning to my neighbors lamp :-) ...YMMV but it is worth getting some clip on ferrites for your motion lights and touch lamps and trying them Dozens of guys selling "ferrites" on Evil-bay for just this purpose

A mismatch results from connecting two different impedances eg. antenna characteristic and transmission surge, any impedance transformer can match the two, but not "reduce the mismatch by
division."

Wrong. The control freak HOA at my last QTH only allowed Christmas lights two weeks before and one week after Christmas. There are no limits to the extent that some people will go to interfere with others' lives. That's the main reason I moved. (I had been inactive for ten years when we moved, so it wasn't a major consideration.)

I had an indoor fan dipole (worked 60 countries with it), and sneaked a screwdriver vertical into the yard with 25 stealth radials in the grass after dark.

It's an issue of field strength rather that the shape of the antenna per se. If one end of a dipole is close to electrical circuits, that may be a problem. Generally, dipoles hang either parallel to the house (eg., inverted V on trees behind the house) or perpendicular to it, with the house as one support (my case). The further away you keep the antenna, the lower the field strength, and hence, the less the interference. Of course, I'm assuming that the antenna is far enough away from the other wires that there is no arcing. The voltage is highest near the ends of dipoles, so that is a consideration.

In the case of the loop, it would be hard to predict without the exact dimensions and frequencies. Internally, the fields from the different legs may add or subtract. Yes, it will be very frequency-dependent, both because the field strength depends on frequency given a fixed antenna geometry, and some devices are more sensitive to specific frequencies. The GFI outlet feeding my Verizon FIOS cable head box would trip on 15 meters until I put a large snap-on core on the AC power line.

My suggestion: buy a bunch of snap-on ferrite cores, make sure you have a good ground at the shack (if you're above the first floor, consider an "artificial ground" like the one MFJ sells), and keep the power at 100 watts or below. Operate and see what appliances need the cores. Put them on, and then buy more.

Topic: 21356 Message: 21406

If you attach about a 30 foot wire to the top of the antenna and pull it away from the antenna it will load much more efficiently on 80 meters... as an inverted L. When you don't want the extra top loading just wrap the wire around the antenna where it will have no effect.

If you fuss with the length you can get the antenna to load on 80 without a tuner. But as long as you have a tuner then having the length somewhere between 25 and 30 feet will be fine. The more you pull it away from the top of the antenna the less length you need...

And you can do the same thing on 160 meters... just more wire. Sure, a 123 foot vertical will have an even lower angle of radiation. But Most of us don't have a way to run a 123' vertical. And the difference between and inverted L and a 1/4wl vertical isn't all that great.

Take 50 feet of speaker wire. Split the first 22 feet and put some tape at the split to keep it from going further. Double the split ends back just enough to tape in a small loop that you can attach strings to. Hang the antenna as in inverted V (from a tree or using a fibreglass pole). Pull the ends out to be a V using your string. Use the remaining 28 feet of speaker wire as your feed line... to a small balun like the very inexpensive LDG 4:1. Using the internal tuner in your radio, or a backpacking tuner this antenna will tune on every band above 80 meters and will outperform almost any commercial antenna (I have them all). Only a Par EndFedz will be close and those are mostly monobanders. This antenna with balun weighs hardly anything and packs in a baggie.

Topic: 21234 Message: 21408

I "elmer" a lot of new hams.

The key questions are where do you live and how "bought in" is your wife?

If you have big trees and some space I'd recommend an off center fed dublet/dipole like the Buckmaster antennas. That way you get practically every band in one antenna without needing a tuner. They work great. Great.

Lacking trees and living in a more suburban environment I often go with a Hustler 6BTV painted camo green. You can barely see one of these if erected right next to a tree, even a short one. Again you get lots of bands with one antenna. While there are better antennas, there are few as simple to get up, as inexpensive or as effective. The thing you need to remember is that "Everything works ... just some things work better than others". A good vertical will get you plenty... I mean plenty.. of contacts particularly on the higher bands. And painting an antenna camo green is 10 times more effective at hiding it than you can possibly believe.

If you really have neighborhood issues or a wife that can't even tolerate a small antenna (yet... they all give in eventually) then you go with a TW2010 portable folding vertical dipole. These are nearly invisible when up, and can be erected and taken down in less than a minute. You just fold them up when not in use.

An alternative to that is a remote tuner (Like made by SGC, iCom of yaesu) feeding a vertical wire or inverted L wire. There is nothing in the air but a bit of wire. I dare anyonbe to either see or object to that little wire.

Now, if you live on a farm and have nothing holding you back at all except not wanting to spend thousands before you know if you love ham radio you get a hex beam, put it on an army surplus crank up tower from Ontario Surplus and then you hang some wires for the low bands. Thats a better station than 3/4's of hams will ever have. And its about $800 for everything.

This is the same as "zip cord." `Zip cord dipoles' were the "the thing" BEFORE WWII when "coax"
was unheard of. I worked with a OM that never used anything else.

There is a special knot to be used where the split ends, it is in older ARRL handbooks tape and
tie wraps are unneeded.

21411. Re: Full wave loop on roof?

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-21 19:00:24 UTC
From: Ashton
Topic: 21386 Message: 21411

Everything works, just some things work better than others.

You can make plenty of contacts using a light bulb as an antenna.

Antennas on or near the roof work. (But this tend to pick up all the noise from the house and maximize RFI problems).

But I'd bet that putting a remote tuner (SGC, ICom , or Yaesu) in a bush and running a wire up over a tree branch would be 1) More hidden and 2) perform better. You would want at least a basic radial system.

I also find that if you use black wire and paint any balun black you can put just about any size dipole up in the trees without anyone ever knowing it is there.

--- In ham-antennas@yahoogroups.com, "Jim Whitaker" <jimawhitaker@...> wrote:
>
> I live with antenna restrictions, but wire strung low to the roof doesn't draw attention. I'm thinking about building a loop at about 9 inches above the roof on PVC sections. It would follow the pitch of the roof peaking about 4 feet higher at the center then dropping back down the other side. Does this seem like it will function correctly or will the sloping plain be an issue? I would just try it but putting up all the supports and springs isn't fun.

No offense KQ0C, but the Hustler 6BTV is a waste of money.

IMHO, it's NOT easy to set up and takes quite a bit of time to tune the traps, presuming you want a low SWR. Even if you place it in an empty field with a quality radial system, you still need to tune the traps for *each* band. This is tedious and time-consuming. And what if one of the bands doesn't "tune" properly. Grrr!

I followed the "instructions" that came with my 6BTV to the "T" and it was the worst experience ever.

Construction quality is poor and the documentation is even worse. I had to dig up on the internet the trap re-tuning instructions as my traps were apparently not calibrated at the factory. (This information was NOT included with the antenna.)

Now perhaps I just got a lemon but it's not a good first antenna.

Shortly after that fiasco, I purchased the Zero Five 10-40 GP vertical antenna and it has worked beautifully. Granted, it's only 40m on up but it works! And it simply defines "quality construction."

No radial wires to mess with and it's footprint is relatively small. You can use your built-in tuner or go with a remote tuner set up. It's very flexible.

You can install the ZF 10-40GP and be on the air in about an hour.

Here's a picture: http://home.comcast.net/~cnick6/1040b.jpg

Topic: 21413 Message: 21413

TV set (old CRT TV) causes noise for HF reception
noise dissapears when I disconnect the coax cable from the TV
the noise is present even the TV is off it seems the power supply still operates even TV is OFF.

I tried ferrite chokes on the coax and on TV power cable in different quantity and different configurations. The only method to stop the noise is to diconnect the TV power cable or the coax from TV.

Any ideas ?

Thanks in advance

Lan

I had a 6BTV and I followed the instruction from the DX Engineering Tech Supplement, which is available on their website, and the antenna worked very well for me. Yes, you have to adjust the traps but it was not difficult.
The antenna is built at the factory to resonate with no radials.
Once tuned, I worked a lot of long haul DX with it, especially on the 30 and 40 meter bands.

Topic: 21234 Message: 21418

I am a huge fan of zero five antennas... I have both the 43 footer and a 33 foot 40 meter monobander. With a remote tuner these are great multiband antennas. BUT they stick up a pretty high, so many new hams can't get away with them. Even your shorter GP needs room for the radial legs.

I have installed 4 Hustler 6BTVs and for every one if you build them to minimum height they will tune just fine. Some experts will realize that this implies that the radial fields I am putting them over are imperfect. The better the radial system the higher the Q of the entire antenna system and the more finnicky they would be to tune. But over a basic radial set up (or a ground rod) they are duck soup to tune. And here in western Colorado where the ground itself has extremely low conductivity almost no one has a really good ground system anyway. The difference between a perfect ground system and a poor one is about 6 dB in real life (I am not comparing to a vertical on the beach in Aruba).

The magic of the Hustler (or your zero five GP) is that it gets you on the air. The key for new hams is to get on the air. Half of our newly licensed hams never do. If you get on the air and start making contacts into Japan and Argentina on 10 meters you get excited. Then you can take all the time in the world to really study antennas and get the last 6 or 12 dB.

The best antenna for a new ham is the one they put up today.

Topic: 21352 Message: 21422

The hill location not only gives you height, but also presumably seperation from surrounding metal objects. It should work a bit better..

Antennas are ideally 1/2 WL up in the air. But after 1/4 wl they work darn well. So either of your choices will "work" just fine.

I'd let aesthetics be a concern here too. Do you really want a yagi on the roof? I like antennas as much as the next guy, but...

And your roof top antenna would be shooting right into your hill in that direction.

Here's a really simple alternative. For $350 you buy one of these
http://www.ontariosurplus.com/other_masts.htm

That gets your antenna to 23 feet plus whatever mast you add above the rotor. It requires no concrete base, guys or anything other that's complicated. If you love the results you are happy. If you love the results so much that you want more you put up a real tower and use this tower for field day.

As long as you are running new coax you might just as well use LMR-400.

> Hi All,
> Am new to this group. I am about to put my TH3 JR beam on the peak of my roof (along the spine). I will only be able to mount it about 5 feet above the peak, so I assume a lot the gain from this antenna will be lost in the roof and the ground. Is it possible to put out a decent signal with this lack of height above the roof? My alternative is to put in on a hill on my property (about 30 feet higher than my roof location) on a short tower, but will have to run about 200 feet of RG8U to it. That is about a 2 DB loss over the roof location. Any help or comments re the better choice? The hill choice is more difficult and more expensive. Thanks. Dave. WA6TXU.

Topic: 21234 Message: 21423

I agree 100% with that statement. I just think for the money and time invested the Hustler isn't a good first choice. Think of the antenna cost plus costs of radials, radial plate, grass hooks, analyzer, etc. That easily adds up to the cost of the ZF antenna.

Any antenna is better than no antenna -- but no one ever said it couldn't be simple.

Yes, I live and die by the KISS method. :)

>
> The magic of the Hustler (or your zero five GP) is that it gets you on the air. The key for new hams is to get on the air. Half of our newly licensed hams never do. If you get on the air and start making contacts into Japan and Argentina on 10 meters you get excited. Then you can take all the time in the world to really study antennas and get the last 6 or 12 dB.

Lan,

This might work for you. An online friend recommended it to another HAM and said it worked great for him.

http://www.21best.com/21_best/electronic/security/video/filters/for_sale_.html#CATV

Read the online instructions to make sure it'll work for you. I don't have any direct experience with this product.

PS. Try calling your cable provider first and complain. They might fix the problem for free.

21426. Re: Flagpole antennas

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-21 20:44:08 UTC
From: Ashton
Topic: 20685 Message: 21426

Do you have any trees?

A 43 foot wire with a 4:1 unun at the base is the smae as a 43 aluminum vertical. In fact zero five sells both.

A 43 foot wire is invisible. Having it hung right by a tree trunk makes essentially no difference. And if the tree isn't 43 feet high you can either shorten the wire or better yet bend it away to another support. Just avoid lengths of wire that are near 1/2 wl on bands you want to use... so no 33 feet or 23 foot antennas.

Your flag pole will also work just fine. But the wire 1) is cheaper, 2) will probably work better and 3) Doesn't invole figuring out how to actually fly a flag off a cobbled together pole. Zero Five does sell flag ploe antennas ready to go... but they are expensive because of the reinforcing necessary to actually fly a flag.

If you do opt for the DX Engineering plan based on the Hustler 6 BTV, they work just fine. They just aren't engineered to handle a flag in 20 knots of wind. So run the flag up a few times on calm days, invite the HOA over to say the pledge of allegiance, and then put the flag away.

I have the same with my girlfriend's crt tv. It causes noise from about 26-28 khz.

The power lines cause qrn on 40 meters.

Better dsp filters, AC isolation transformers, diversity receive capability is the secret to good noise suppression, just not cheap. Ferrites on power supply leads, good dc and RF grounds.

Disconnect the TV permanently.

The radio is much more fun.

Your kids will grow up smarter than all their friends.

You and the wife will actually talk.

And the dog will get to go on many more walks.

Thanks Chris
I'm trying hard to get away from running with an ATU, I've arthritis in my spine and shoulder, so turning rollercoasters is a pain. Motorising it would be expensive.
Its a toss up between OCFD and 40mtr CFD with a 20mtr trap, then nested delta loops for 17,12 &10 mtrs

21437. [ham-antennas] Math thread has lost it's way, please read. Moderator

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-22 03:34:21 UTC
From: van wd8aam
Topic: 21415 Message: 21437

Statements on this "Math" thread have gone off the track.

Please return to subjects/threads that pertain to Ham-Antennas.

Political and/or Religious/ statements especially have the ability
to inflame others of different persuasions. Therefore, limited
Holiday good wishes are as far as the groups may carry these
comments, and political comments are prohibited.

Thank you, and now back to the approved comments/questions
relating to Ham-Antenna subjects......

Van Lincoln, moderator, end of commentary.

21438. Re: [ham-antennas] Re: multiple OCFD

Richard, the OCFD will require an ATU of some type. You can get a auto tuner from LDG, MFJ, SGC,ETC
If you have room for a 40 meter Center fed dipole coax fed, go for it. At 7.1 you should have coverage 7.0 to 7.2 Mhz.
Add a full size 20 meter dipole in parallel with it fed from the same c oax.
You should install it as far from the 40 meter dipole as possible to reduce interaction.
I have used this type antenna for 80,40, 20 and 15 for over 50 years. I now have 17 dipole added also.

I have not had good fortune with trap dipoles, too narrow SWR bandwidth, higher SWR and lots of fussing
to get iot tuned. I don't recommend them unless you do not have room for a full size dipole.
If you set the 40 meter antenna for 6.7 to 6.8 Mhz, it will also work on 15 meters but the SWR may
be a bit higher on the phone portion of 40.

BTW, DMSO helps my arthritis. I get it at a VET supply place. They use it on race horses when they get lame.
Just rub it on like linament.

Dr Don HC4/W4BWS

Whilst I applaud the sentiment of visiting a memorial cemetery I do wonder what this has to do with antennas? As for the comments about liberals that is politics and has nothing to do with Amateur radio and under the UK license conditions is a prohibative subject in communications.

Hi Don
At the moment I've a dual band 20 & 17 mtrs CFD, and a reasonable match to 50 ohms by inserting 1/12 wavelength of 75 ohm coax Fc 18.1 MHz between the feed points, and the separation distance is 6".
I've found the male BNC to two terminal adaptors very useful for centre dipole connectors, albeit not to strong, but great for experimenting.
Most of my operation is SSB or psk31, so may get away with adding a 40 mtr CFD, to give the top end of 15 Mtrs.
I'm increasing my activity on HF to compensate for the extremely low activity on VHF in the UK, Its now either EME, and this QTH is too noisy, or us HF more.

Does anyone know how much power PTFE RG174 can handle in practise if air cooled, its not so heavy as RG58/9 for matching stubs/lines, UK limit is 400W.

All noted on DMSO :)

While I agree that this seems a little off topic. The Cemetery is not in the UK so I do not see what that has to do with the post. Besides this is a computer based mail list not a ham radio. So unless the Moderator or Owner finds that this topic should not be put out to the group then that is his right. UK laws about this has nothing to do with what was written.
Just my view about the post.
James

From: Jim Whitaker
Topic: 21444 Message: 21444

Let me see if I have this right, The ladder line after the Balun will be much lower loss with high SWR then coax. I assume that the remaining coax feed before the Balun is still involved and presents a much higher loss per foot. So I want to mount the Balun with as little coax as possible and run most of the feed as ladder line? Is this why mounting the balun at the antenna feed point isn't preferred?

de n8xyn Jim

Topic: 21444 Message: 21446

Right point!!!

For multiband use you tune THE WHOLE SYSTEM
Antenna, ladderline (if any), balun, coax, tuner, coax, swr-meter,coax,rig

If swr is low the losses are low
If swr is high then losses are higher BUT
Ladderline with high swr has lower loss as coax (even if on coax the swr is low)
As it is not easy to climb a tower for tuning the antenna at the fedpoint
And remote tuners are not cheap
Best way is to have ladderline down to the shack
And a short run of coax from tuner to outside balun
Or best way a balanced tuner with balun on the input and ladderline IN the shack

Subject: Re: [ham-antennas] Fwd: [Freedom_of_Information] Fw: [Defeat_Liberals] Christmas at Arlington Cemetery

While I agree that this seems a little off topic. The Cemetery is not in the UK so I do not see what that has to do with the post. Besides this is a computer based mail list not a ham radio. So unless the Moderator or Owner finds that this topic should not be put out to the group then that is his right. UK laws about this has nothing to do with what was written.
Just my view about the post.
James

Whilst I applaud the sentiment of visiting a memorial cemetery I do wonder what this has to do with antennas? As for the comments about liberals that is politics and has nothing to do with Amateur radio and under the UK license conditions is a prohibative subject in communications.

Subject: [Defeat_Liberals] Christmas at Arlington Cemetery

Merry Christmas Everyone

CHRISTMAS AT ARLINGTON CEMETERY

I wonder why the press hasn't enlightened the public

about it??

Arlington National Cemetery

Rest easy, sleep well my brothers.

Know the line has held, your job is done.

Rest easy, sleep well.

Others have taken up where you fell, the line has held.

Peace, peace, and farewell...

Readers may be interested to know that these wreaths --

some 5,000 -- are donated by the Worcester Wreath Co. of

Harrington, Maine . The owner, Merrill Worcester, not

only provides the wreaths, but covers the trucking

expense as well. He's done this since 1992. A wonderful

guy. Also, most years, groups of Maine school kids

combine an educational trip to DC with this event to

help out. Making this even more remarkable is the fact

that Harrington is in one of the poorest parts of the state.

Please share this with everyone on your address list.

You hear too much about the bad things people do.

Everyone should hear about this.

Subject: [ham-antennas] Yet one more Balun question please?

Let me see if I have this right, The ladder line after the Balun will be much lower loss with high SWR then coax. I assume that the remaining coax feed before the Balun is still involved and presents a much higher loss per foot. So I want to mount the Balun with as little coax as possible and run most of the feed as ladder line? Is this why mounting the balun at the antenna feed point isn't preferred?

de n8xyn Jim
Thanks

That is the way I understand it Jim. I keep my coax just about 2ft long. Many tuners have a built in balun so you can run the ladder line right to the back of the tuner. My MFJ tuner built in balun would not go down to 1:1 on all bands so I built my own. A foot or two of coax won't have a lot of loss like it would if you had your balun mounted at the antenna.

Some people are just stupid.

"Freedom of Speech" is about stopping government interference. It has nothing to do with the use of private property (which yahoo is and individual groups are).

Intelligent people recognize that there is a proper time AND PLACE for certain discussions. Would you stand up in church and demand the right to speak about antenna design or Smith Charts because of "freedom of speech"? Hopefully everyone has more common sense than that.

Well, same thing here. This is not an appropriate forum for religious or political discussion. Mature people realize that.

Hi mike

simplest is dipole and work on fundamental and odd harmonics, Fan dipole as multi-band I use an Off Centre Fed dipole (Carolina Windom) in a "V" strung between my house and Walnut tree at lowest about 12ft off ground and that works for me. Bragging hat on now as on Monday got ZL4 on 100w ssb on 17m only my 2nd ZL so happy. Seriously have a play. Wire is relatively cheap, everybody's QTH is different so try. Oh I would also have a vertical if possible as although they can be a bit noisy they tend to have lower angle radiation than an horizontal when at low heights.

If you want to do some reading I would recommend the following for ideas in no particular order:-

Antennas from the ground up, Cebik vols 1 & 2

Simple and fun antenna, Hutchinson and Straw

Backyard antennas, Dodd

Practical wire antennas, Poole Vols 1 & 2

and the daddy of them all the ARRL antenna Book

being as Santa is a couple of days away might be an idea for last minute present?

I have an 80 meter loop hung at about 25 feet which works well on all bands from 80-10. It is 265 feet of wire, held up by insulators at the 4 corners. Fed by about 35 feet of 450 ohm ladder line to a 9:1 Balun... then coax to the radio. Only need to tune on 80 meters.

You can feed the same antenna directly with coax and it will tune well on 80 and 40, but need a tuner for other bands.

You can calculate the lengths of smaller loops using this "calculator"
http://mysite.verizon.net/ka1fsb/loopcalc.html

The best tuner for balanced lines would be a balanced one such as
the AT502:

http://www.hamware.de/hardware/tuner502/at502-e.htm

It has the balun at the input, always running at low SWR.

Yes, you have it correct.

For many of us, it is more convenient to run coax outside than to bring open wire or ladder line inside.

Once you get outside, it is generally better to run open wire or ladder line if the antenna is not matched to coax, or has a very long run.

For a single band dipole not too far away, I would probably run coax all the way. But for a single antenna wire operated on multiple bands (e.g. an 80m dipole operated on multiple bands), it's probably best to run as little coax as convenient to the balun, and open wire or ladder line the rest of the way.

Mike , one small question, what size loop can you put up?

I have a “No Tune” loop that works 40 thru 10. It is a little different. Here is how I made it. I put up a 80M size delta loop. I feed it with coax and have a 4:1 balun at the apex. The apex is about 40ft and the other two points are about 25ft. I used pulleys and rope at all points for quick adjustment. It is spliced in the middle with a split bolt. A 80m loop is a 100 ohm antenna but when operated on a multiple frequency it is a 200 ohm antenna so a 4:1 balun matches it to 50 ohm coax. I checked it at the area of the 20M phone band where I work and adjusted it to a 1:1 SWR. I now can work 40, 20, 17 , 15 , 12 and 10 on one antenna. The low SWR point on 17 is a little low in frequency but all other bands are great. 17 is fine with a inboard tuner if you have one. If you try this remember if you are adjusting for a good SWR setting on 20 and are inclined to use math to figure the length needed for adjustment that you will be adjusting a 80M antenna so if you think you need 4 inches of trim by ciphering it will be 16 in the real world.

Well it might be a good set up but for the tuner and control unit for use
with a amp is a little over $3000 and my MFJ tuner cost a whole lot less and
I made my own switchable 4:1 or 1:1 balun for just a few dollars.

21463. Back to the radio topic...

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-22 16:53:05 UTC
From: Dave Cole
Topic: 21439 Message: 21463

Hi,

To bring this back to ham radio... Can you expand on the prohibited
topic thing? I have never heard of that. Either on list, or off list,
you call.

Dave
NK7Z

21464. Re: [ham-antennas] Re: multiple OCFD

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-22 16:56:54 UTC
From: Don Sanders
Topic: 21392 Message: 21464

Richard, most users of OCFD antennas have a tuner in their radio or external.
Moving the feed point affects the balun needed for coax feed. 4 to1 or 6 to 1.
The height above ground also affects this, lower needs 4 to 1, higher 6 to 1.
While I have used a Carolina Windom quite sucessfully when I lived in Alabama,
as I had it up about 70 feet in the pine trees, I found it did not work well here as we have no high trees.
Thats why I went back to the parallel dipoles at 35 feet on bamboo poles.
I like the ability to QSY with in the phone band or CW band with out retuning the rig or amplifiers.
I use the tuner with my 88 foot doublet for working all bands as it is at 90 degrees to the parallel dipoles.
Its path is over salt water to ASIA and S. Pacific. The dipoles favor the US and Europe.
Math is not difficult regarding basic antrennas. Simple Algrebra in a few formulas is all that is required.
If you want to become a true whiz then you can tackle Maxwells, Crosse, and other theoretical texts.
They are not necessary to understand basic antennas.
Just read articles by CEBIK, other authors on Ham Universe or other web sites about various antennas.
You will begin to understand the basics shortly.
The ARRL Antenna handbook is another good resource for info.
I recommend reading an older issue from the 1960s as well as 1990s and 2007 or 2009. They all present the info
somewhat differently and sometimes it is easier to understand in one or another issue.
I also find the latest info somewhat dumbed down but different issues show different antenna projects.
The RSGB Handbook I find extremely useful as it presents information not given in the ARRL books.
Like wise the RSGB has books by Moxon and others that give good info on antennas.

Antennas are not all "rocket science" unless you want to get deep into how they operate and do esoteric design work.
However a good understanding of the basics is helpfull to keep a head full of hair and a deep color.
It has been a second love for me for over 60 years and I worked over 30 years professionally in RF and antennas.
You have a good start being here as there are many with good practical advice available. But do your own investigations.

IT'S FUN!!

if you run less thaan 500 watts check out the LDG AT-600 pro if more than 600 the LDG-1000 pro . no rollercoasters to turn .

21466. Looking for antenna

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-22 17:09:30 UTC
From: Ronald Anderson
Topic: 21466 Message: 21466

Anyone on the reflector got a Force 12 - C-3 or EF-220 for sale under
$250.00, I have a friend who /HR9 on the island
of Roatan, Bay Islands, HN, the only mode of transportation is via boat.
Anyway he doesn't have a lot to spend on a
antenna so he is looking for a used one in good shape. Thanks for the help.
You can reach me off line and I will have
him make e-mail contact.

Thanks for all the replies and help.
Definitely food for thought,
The 1.5mm aluminium wire arrived today at last, and I strung up a 40 mtr CFD, From nearly the top of the
tower to a tree in the corner of the garden, about 25' high.(there's a pic of the tower and antennas on
qrz.com)
I tried the multiple dipole for 20 & 17 mtrs at the same feed point, not much interaction on 40 mtrs ,
but both of the high bands no longer resonated well. But if I leave them off I can get some height on it
without drooping, and less tension on the stub mast on the tower.
There's a long run 40' of RG213 which goes underground until the middle of the garden/yard, then about
35' of RG58 to the feed point, there's no balun at the feed point at the moment. With 90W forward I
have 200mW reverse power. So I'm tempted to leave it well alone and look for another point to hang
antennas from for the high bands.
On 15 mtrs not so good , its resonant at 22.3 MHz. Maybe a series resonant trap at 21 MHz at each end
to add a bit of length ?

I agree. The terms and conditions of joining the forum was to keep the subject matter on the forum for which it was generated. If the religious thumpers want to talk about their religion or religious matters, there has to be a yahoo group for them. This one was generated for ham radio antennas. Common courtesy should dictate that this will be the subject discussed.

While I'm a Christan, I think this post does't comform to the rules of ham antennas!

It's not a forum for your religious beliefs, comments, etc

My .02 worth!

That's what I suspected to be true. Now is there any difference other then power handling between say 300 & 450 ohm ladder line?

Yes ... the impedance of the ladderline does also change impedance on lower end of the line (so at the balun end) ... 450 has lower loss, higher power capability and the impedance will keep you in the middle of the impedance ranges so easier to match

You can get them any place, I have no ties to R&L but I would call them, the carry at least 6 different brands of 5/8wl 2m mobile mount antennas, magmount, trunk mount and whatever. So you have many to choose from.

I mounted a "v" wire beam on my roof on a12 foot mast attached to my chimney. I fed it with 300 ohm twin lead. Each leg is 133 feet long, attached to 2 trees. The angle between the legs is about 45 degrees, with the open end facing southwest and the closed end, northeast, of course. It is a bi-directional antenna, but I suspect the greatest gain is at the open end. The gain is about 2 db on 80 and up to 8 db on 10. I think I am conservative with these figures. The twin
lead goes to my tuner which has a built in balun. Downside is that it is pretty directional. I live Georgia, so it is great to Europe and New England, and and to Australia. Not good to Japan or Africa.

Mike,

You did not mention what you are trying to work. Are you trying to work DX, contest, or just make contacts?

If this is just a temp situation I was use a small homebrew G5RV. 33' feed with 33' of ladder line.

Harold/KD8DVY

>
> I have a â□□No Tuneâ□□ loop that works 40 thru 10. It is a little different. Here is how I made it. I put up a 80M size delta loop. I feed it with coax and have a 4:1 balun at the apex. The apex is about 40ft and the other two points are about 25ft. I used pulleys and rope at all points for quick adjustment. It is spliced in the middle with a split bolt. A 80m

loop is a 100 ohm antenna but when operated on a multiple frequency it is a 200 ohm antenna so a 4:1 balun matches it to 50 ohm coax. I checked it at the area of the 20M phone band where I work and adjusted it to a 1:1 SWR. I now can work 40, 20, 17 , 15 , 12 and 10 on one antenna. The low SWR point on 17 is a little low in frequency but all other bands are great. 17 is fine with a inboard tuner if you have one. If you try this remember if you are adjusting for a good SWR setting on 20 and are inclined to use math to figure the length needed for adjustment that you will be adjusting a 80M antenna so if you think you need 4 inches of trim by ciphering it will be 16 in the real world.

21480. anyone used or heard of using 20/22 ga galvanized fence wire for antenna wire?

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-23 05:53:54 UTC
From: kj6ddf
Topic: 21480 Message: 21480

I have heard of using using steel galvanized 20 or 22 or similar for antenna wire?

21481. Greetings all new to group old to antennas

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-23 06:28:48 UTC
From: ko1h
Topic: 21481 Message: 21481

HI All, Im new to the group but Ive been building antennas for almost 40 years. Im currently pondering about two antenna posibilites. I have a Windom across the front tree''s of my very small lot that is not working as it used to. Its primary use had been to cover warc bands and as a General use antenna for my upstairs stations. (main Station in office in basement SO2R etc) Upstairs station for casual dxing while watching my son. (5 yo now in kindegarten)

Considering the following to either replace the Windom with another, replace it with a G5rv or install a double sized g5rv or 160m dipole fed with twin lead(The larger antenna would have a configuration something like this.

A 60ft section center or off center fed at apx 35ft in the front broad side e/w with the two legs bent 90 degree for another apx 60ft sloping down to about 20ft wiht the remainder of the antenna being bent in again paralell to the front wire again at apx 20ft.

Not quite sure if I should leave it a doublet or turn it into a loop?

Not sure if its worth the trouble. I have other 160m antennas.

Sugggestions?

Just to give you an idea of what else I have:

Here is the current atnenna line up:

2 element quad 10-15-20m
4 element tribander fixed south (currently down but to be reinstalled in spring)
2 element vertical phased array on 40m
80m center loaded gladiator
Ma160 Top loaded vertical
40-80-160m loaded dipole
Dxa sloper
60m dipole
10m delta loop
10-12-15-17-20 vertical dipoles
30m vertical dipole
30-17-12 m invertred v fan dipole

Inductivly loaded 160m Inverted L with loaded elevated radials

4 elements on 6m
13 elements on 2m
25 elements on 432
10 elements on 220

Fm Verticals

Lets see what the opions are detween Windom, G5 or bent dipole or loop?

thanks es 73 de John ko1h

20 ga sounds way too thin for fence wire. Anyway, typical galvanized fence wire has thin galvanizing and doesn't hold up well, besides being harder to make a good connection. Why not just use copper wire? You can get rolls of #16 THHN insulated wire at Lowe's etc. for as little as 10 cents/ft.

At what frequency and how high in the air.are you considering?
Interested in working DX or just having a bigger signal on the local
NET, etc.? Proper design (length , apex angle and height above ground
are all important). Based on the available space and trees, it is worth
modeling your situation to see if the pattern does what you want

Many folks throw up a couple of hundred feet of wire at modest heights (
say 35-40 feet) and are disappointed that it doesn't give them 3 s-units
of gain on 80M when working Europe., an unrealistic expectation given
the height in my example...

Make sure your R and XC or XL values of your actual antenna measured with a Noise Bridge OR ANTENNA ANALYZER are within the adjustment ranges accepted by your tuner,refer to your units specification sheets

Remember its only fooling your radio into thinking it a good match exists. Better to get the antenna within band parameters.

Actual site conditions can throw OFF the theoretical antenna THEORY.

kj6ddf wrote:

> I have heard of using using steel galvanized 20 or 22 or similar for antenna wire?

And I tried it, (electric fence wire) it worked fine. The thin electroplated zinc plating was
damaged on the top by atmospheric electrical energy* way too early. If it had a plastic coating it
might be practical. It was very hard to see up 30'.
* from nearby thunderstorms

The very thinnest stainless steel wire or cable (stranded) should overcome such problems, but the
strength of solid wire depends on the type of stainless steel it is made of.

Bragging hat on now as on Monday got ZL4 on 100w ssb on 17m only my 2nd ZL so happy. Seriously have a play. Wire is relatively cheap, everybody's QTH is different so try. Oh I would also have a vertical if possible as although they can be a bit noisy they tend to have lower angle radiation than an horizontal when at low heights.

21487. Re: [ham-antennas] Re: Antenna(no tune)

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-23 13:47:12 UTC
From: Memwl
Topic: 21452 Message: 21487

I do have the yard for that now, maybe I can use PVC to support at the wire, its just that I have a power pole on the east side of the yard 50' x 60' about center. it has a Power and a cable drop coming to the house, its to high to go over it so the wire will pass below the power lines.
I also have guy wires on a imax that I use for 10 meters, the wires are wire, so I will change those to
some type of nonmetallic support, I as just wondering will I get any noise off the power and cable drops, if so I will try the beads
I will take a picture and try to upload it, maybe someone has a suggestion.

Thanks for any input
ke7sbe
Mike

Rich 40-10 would be ok for now, I appreciate your input, I have been going round and round and just have not settled on what I want to do
I am getting restless, so I am just going to start experimenting, with some of the ideas I get here

Thanks

>I have a “No Tune” loop that works 40 thru 10. It is a little different. Here is how I made it. I put up a 80M size delta

loop. I feed it with coax and have a 4:1 balun at the apex. The apex is about 40ft and the other two points are about 25ft. I used pulleys and rope at all points for quick adjustment. It is spliced in the middle with a split bolt. A 80m loop is a 100 ohm antenna but when operated on a multiple frequency it is a 200 ohm antenna so a 4:1 balun matches it to 50 ohm coax. I checked it at the area of the 20M phone band where I work and adjusted it to a 1:1 SWR. I now can work 40, 20, 17 , 15 , 12 and 10 on one antenna. The low SWR point on 17 is a little low in frequency but all other bands are great. 17 is fine with a inboard tuner if you have one. If you try this remember if you are adjusting for a good SWR setting on 20 and are inclined to use math to figure the length needed for adjustment that you will be adjusting a 80M antenna so if you think you need 4 inches of trim by ciphering it will be 16 in the real world.

20/22 gauge is too small . I have used the 1/16 " lift cable for years .
the only problem I ever had is the connection point between the cable and the 450 ohm line
. have to clean it occasionaly and keep anti oxidation grease on it .

20ga would be OK for a 10M or 15M dipole but around here 17ga & 14ga is standard at all the farm supplies and hardware stores.

Another option is Aluminum fence wire.

It's MUCH lighter and just as strong. I have had a 600 foot loop up for
going on four years made from the stuff now.

I have 2 antennas made from 14 ga gavanized steel electric fence wire. costs $48.00 for a half mile long roll of the stuff. Both my antennas have been up now for 3 years here in missouti and no problems with them yet. My loop is 1200ft long supported by 5 55ft towers located around the 6 acres i have. the long wire is 375 ft long with no center support. the towere are approximately 220 feet apart. no broken wire after 3 years . have worked all states on 20m,40m and lack AK on 80,.23 different DX countrys. I would say use the electric fence wire.

21494. Coax for Loop antennas V factor etc

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-23 15:11:05 UTC
From: ko1h
Topic: 21494 Message: 21494

Hi all Well decided I would try a :Loop antenna as per my previous post. Now I need some input on Velosity Factor.
If I make the loop out of Rg-174 or RG-58 etc. How do I configure it to take advantage of the Vfactor for making it electrially longer than it physically is? Do I just use the center conductor? Do I short it at one end? Do I short both ends?

Help an old man out...

I think most people would make the loop out of standard antenna wire. One reason to do so would be to reduce the weight aloft and the resultant sagging.

Date: 2011-12-23 17:30:06 UTC
From: fly_ul
Topic: 21476 Message: 21497

I plan to build the antenna in the April 2011 QST with a few changes.
The antenna will have 4 120 foot legs 45 degrees apart. It will be 44 feet at the center and 11 feet high at the ends. It is switched to change the direction. According to the article it should cover the world. I plan to use it on 20 - 10 meters for dx.

Do you think this will work?

Topic: 21452 Message: 21498

The ARRL antenna book is good reference. If money is tight you can always wait until the next hamfest and pick up a used one for a few dollars. The basics never change, I have some ARRL antenna handbooks for the 1970's and the math and basic information is the same as today's book for a whole lot more.

In the meantime read all the links at http://www.ac6v.com/antprojects.htm, you can print out information on what you like and make your own antenna book. It might take a day or two over the Christmas holidays to read all of his links but I am sure there will be a few you like and the price is right. Also see http://members.fortunecity.com/xe1bef/

This is how I keep a reference for myself , that way when I go to build I have it in front of me. When you get my age you forget what you wanted to build, so the book helps.

Rich ,KDØZZ , ☺

The likelyhood of damage to a component is inversely proportional to the number you have available, and directly proportional to its cost.

>> I have a “No Tune” loop that works 40 thru 10. It is a little different. Here is how I made it. I put up a 80M size delta loop. I feed it with coax and have a 4:1 balun at the apex. The apex is about 40ft and the other two points are about 25ft. I used pulleys and rope at all points for quick adjustment. It is spliced in the middle with a split bolt. A 80m loop is a 100 ohm antenna but when operated on a multiple frequency it is a 200 ohm antenna so a 4:1 balun matches it to 50 ohm coax. I checked it at the area of the 20M phone band where I work and adjusted it to a 1:1 SWR. I now can work 40, 20, 17 , 15 , 12 and 10 on one antenna. The low SWR point on 17 is a little low in frequency but all other bands are

great. 17 is fine with a inboard tuner if you have one. If you try this remember if you are adjusting for a good SWR setting on 20 and are inclined to use math to figure the length needed for adjustment that you will be adjusting a 80M antenna so if you think you need 4 inches of trim by ciphering it will be 16 in the real world.

Topic: 21480 Message: 21499

For those of you using or considering using non copper wire for antennas, don't forget the "skin effect" at RF. At HF frequencies, the current flows on the very outside of the conductor. A 14ga wire has the same effective resistance as a much smaller conductor and therefore higher resistive losses. When you go to a non copper conductor, the skin resistance (and resistive losses) is even higher.

Does it make a real difference? I don't know the numbers, but I would imagine there will be some measurable losses. Personally I'll stick to copper for the slight additional cost.

Those numbers are not supported by the ARRL Antenna Book.

On 20m, the legs are 1 wavelength, which at the optimum angle (100 degrees) will give you 3db of gain. On 10m, it's two wavelengths and 70 degrees will give you a hair over 4 db of gain.

"Gain" on 80m? I don't think so.

Don't forget, there is no free lunch with "gain". A beam only gets gain in one direction from stealing it from other directions. So unless you have a fixed direction that's important, you need a rotator or you will lose as much (in most directions) as you gain in one direction.

*Aluminum is an excellent choice. I started a similar thread a few weeks ago (in this group?) and I was informed that aluminum fence wire works very well. It won't corrode (at least not up in the air). Aluminum is actually a better conductor that copper, isn't it? Here's the best part: it's only $5 for a roll of 500 feet at Home Depot. I'm sure any place that sells Home Depot-y stuff would have it pretty cheap, too.

There are some solders (and brazing materials) that will join copper to aluminum, but the best bet might be to crimp or clamp the wire to your feed line.

If you have room for a topband loop ... why not try it
I love my loop
Very quiet in receive (low noise)
Fed with ladderline also good on the other bands

I definitely agree! I grab my 1964 copy of the Antenna Book a lot more often than the newer one. It's much easier to find things in the older one but then off course, it's been well read over the past 48 years :)

As you said, the basics don't change.

From: siegfried.jackstien
Topic: 21473 Message: 21505

Why 5/8th ??? there are several other designs that perform equally or better

I have a dualbander that is 1/2 wave on 2m and 2x 5/8 on 70

Works really good even without any car under it (radialless so to speak) or
on a magnet mount ...

5/8 is made electrically longer with a coil to 3/4 ... and so there has to
be a good ground under the antenna (high current point)

So in some cases there are really better designs than the 5/8th

Use Anti-Ox at all connections.
Let it kink and it will be splice time. (lineman's knot)

21509. Help with beam antenna

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-23 21:05:24 UTC
From: Dwayne
Topic: 21509 Message: 21509

Hello All,

This is my first post to the group, and hopefully I will not dork it up.

I have always used wire antennas up to this point. But recently I was given a beam antenna.

It is a Hy-Gain TH-4 best I can tell. Did not get paper work with it.

Did get the manual on line for the TH-4. (looks the closet to what I have)

Here is my problem.

When I set up the beam at four feet off the ground, I can get the SWR perfect for the three bands, (10/15/20)

using an antenna analyzer.

However, when I put it up at 15 feet to test it for a week, SWR changes to no good. Back at four feet they are great.

I know height above ground makes some difference, just not sure how to make the adjustments before it goes up.

Any help is appreciated.

Good question! One thing you can try -- point it straight up in the air when adjusting at 4'. It will lessen ground effects.

The "ground" (dirt) is absorbing the antenna analyzer's power like a resistor.
The antenna is not in tune, when it is up 15 feet which way was is it off, it could be either way.
Start by pointing it up with as much space under the reflector as possible and tune it.
Then put it up as high as you can test it and note the direction of error, drop and tweak.
You are a quarter the way done already. Good post!

Dwayne,

height above ground does NOT make SOME difference, it makes a BIG difference. especially when it is that low!

The ideas others have provided (point it up and get it as high as possible) will help some but the best way is to get it up to working height, and figure out where the lowest SWR is. If it's at 14.350 and you want it at 14.200, then you have to adjust the 20m element 150 kHz. Then put it back up at your working height and see what it looks like. And so forth.

Good luck,

Ken WA8JXM

I didn't see what band you were thinking of, or whether you where thinking of a long wire loop or a
magnetic loop.
RG174 is not strong enough to support its own weight on an long unsupported run.
If you where considering a magnetic loop, for the lower bands the diameter of the conductor starts to
become very important.
If that was your intention to build a mag loop, find one of the Hams with large VHF/UHF arrays and
enquire if the know of any water damaged 1/2" heliax/hardline. These guys have normally got their ears
to the ground where there are sources of 1/2" hard line.
The reason I say water damaged is that PTFE foam coax is pretty useless once water gets in, and is most
times thrown out. Cell phone sites will have regular maintenance, which sometimes makes some available.

It makes great low band mag loops ,bends easily into shape and you can join it with low cost 1/2"
plumbing fittings, you only use the outer corrugated braid, so water damage doesn't matter.
I use a 16' dia mag loop made from LDF4-50 on 80 mtrs and 160 mtrs, and requires minimal mechanical

support.
Now I've probably confused the hell outa you all.

Lowes and home depot seem to have the worlds worst web sites. These web sites fail to indicate
the materials used and the thickness, insulation materials used and the thickness is also neglected
similarly.
At homedepot.com I found: "OOK 50 ft. Aluminum Hobby Wire Model # 50176
Internet # 100192917 Store SKU # 396300 Store SO SKU # 285742" with no mention of wire thickness.
BTW: 50 feet is $3.48 and:

"FARMGARD 1/4 Mile 17-Gauge Galvanized Electric Fence Wire Model # 317754A Internet # 100322493"
is: $13.85 (1,400+ feet)
This is about $5 for 500 feet. This is Galvanized Steel Fence Wire.

I could not find any `aluminum electric fence wire' at: homedepot.com

Thanks Richard I will keep that in mind for a Mag loop. But I was considering a regular loop. My inclings have been confirmed. Thanks all for the V Factor clear up. It had been bothering me for many years.

I didn't see what band you were thinking of, or whether you where thinking of a long wire loop or a
magnetic loop.
RG174 is not strong enough to support its own weight on an long unsupported run.
If you where considering a magnetic loop, for the lower bands the diameter of the conductor starts to
become very important.
If that was your intention to build a mag loop, find one of the Hams with large VHF/UHF arrays and
enquire if the know of any water damaged 1/2" heliax/hardline. These guys have normally got their ears

to the ground where there are sources of 1/2" hard line.
The reason I say water damaged is that PTFE foam coax is pretty useless once water gets in, and is most
times thrown out. Cell phone sites will have regular maintenance, which sometimes makes some available.

It makes great low band mag loops ,bends easily into shape and you can join it with low cost 1/2"
plumbing fittings, you only use the outer corrugated braid, so water damage doesn't matter.
I use a 16' dia mag loop made from LDF4-50 on 80 mtrs and 160 mtrs, and requires minimal mechanical
support.
Now I've probably confused the hell outa you all.

Try far supply places.

Mine is like the 17 ga and is made for tension on it. It is made to be
pulled tight.

Last storm it did not break it broke a 4" diameter branch the rope was
going over!

Acording to the ON4UN low band dx book the galvanised wire has an RF resiastance much greater than copper or copperclad steel wire. It will drop the antenna efficiency to about 88%. Lets see, 88% vs 1 % for no antenna is a significant improvement. That is way improved over the proverbial "wet string". And if you can save enough to take the wife out to dinner and theatre you are 1000% improvement.

I agree with Dave.

I just finished making one in time for the 10m contest: monoband, swr less than 1.2:1. I made 25 dx contacts, which include eastern Europe. I ran a Yaesu FT-857D portable. So I have to say they're great.

There's a picture on QRZ under my call sign.

21523. Update on my 2 WL 160M Loop Antenna

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-24 01:55:57 UTC
From: goldtr8@charter.net
Topic: 21523 Message: 21523

First Merry Christmas to everyone!

Gents,

I am now with 2 days of playing with the 2 WL loop in comparison to my dipole. I finally had the chance this week to add the additioinal 250 FT to my loop to get it to 2 WL.

I wish to thank everyone who gave me support and insight analizing data from my first attempts with the loop low to the ground, then with the spud gun to get the wire re-run and finally now a correct length.

I am hearing stuff with the loop that is totally in the noise with the dipole. Second I have made some DX contacts to HI from MI on 20M to a portable that I gave a 5x2 signal report that I could not hear with the dipole. Plus he gave me a 59 with his portable set up. To me working someone with a compromise temporary antenna is pretty neat, as I usually consider myself the guy with a compromized antenna.

I was able to work 160m last night as the tuner was able to get a match and I was heard in NY from MI running only 100W. I cant use the amp on 160m as the tuner is unhappy with any kind of power and the amp protects itself. Good thing the amp is smarter than me.

I have been playing on 80 and 40 and getting fantastic signal reports with this setup. On 80m guys running barefoot sound like they have amps turned on compared to the dipole.

I am also working lots of mobiles with this antenna as I can hear them now, where in the past I never seemed to work mobiles.

I still have some matching issues to deal with, as I am not sure if I have to modify the feed or I need a 4:1 balun instead of a 1:1 in order to get better matching for low SWR..

Anyway its up it works and I am extriemly pleased with the results so far.

Again thanks to all for your advice and encouragement.

~73

21526. are there any PL-259 connectors still made in the USA?

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-24 08:10:19 UTC
From: kj6ddf
Topic: 21526 Message: 21526

I wonder if anyone knows of anyone who still makes connectors- PL-259's in the USA?
Or perhaps Japan?

And as I understand it, even Amphenols connector are now made in China, as I understand it, it has something to do with EPA regulation, or I suppose what that means, EPA Made manufacturing so expensive, that they could not compete any more?

I asked my Coax supplier recently who uses genuine US made times microwave but the PL-259 connectors are made in Taiwan

Which is (I think) better than China, but that's an overall generational, it may be something made in China might be made very well? But I generally feel much better when I read made in Taiwan.
Still I'd like to find out if there is someone who makes them in the US or Japan
Steve

Lan,

This might work for you. An online friend recommended it to another HAM and said it worked great for him.

http://www.21best.com/21_best/electronic/security/video/filters/for_sale_.html#CATV

Read the online instructions to make sure it'll work for you. I don't have any direct experience with this product.

PS. Try calling your cable provider first and complain. They might fix the problem for free.

21528. my first antenna

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-24 11:38:54 UTC
From: kj6ddf
Topic: 21528 Message: 21528

Well I don't have it yet,

but I ordered a "store bought" 160 meter loop with 124 ft ladder line

the house has a tall roof, I used to climb trees when I was old enough to reach the lowest limb, perhaps 5 years old and later I was an Ironworker, and even if I shouldn't, because I have back and neck problems I climbed up onto the roof.
I was still scared, which showed my brain was working just fine.
I don't know if I'm up to putting the antenna up myself or not.

The top of the roof must be 30 or 35 ft high, there are several trees in the back yard that are possibly useful, but aren't very big trees. The wire is 14 ga with insulation, so it's probably on the heavy side.

If I only hung it from 4 points, I'd have to have strong trees or if I am able to use the top of the roof as two points for the front.

Maybe I can put more insulators, I might go over the top of the garage, and that would be an additional insulator and maybe if I added several more so there wouldn't be so much weight on the one in the back yard all the way in the back, north west side.

Then over to the other side of the back yard, or the north east corner, I'm not sure which tree, but there is a large red oak tree, and from there I'm not sure. When I first measured off the yard, it's roughly 120 ft x 110 ft, so I may have more antenna that yard, unless I spread it or fold it a bit, I'm told I can do that.

It's interesting, I get all sorts of advice from knowledgeable people, and I understand, (most of the time) what they are talking about, but when I go to talking about what they advised me to do, I can't say it very well.

Anyway, from the top of roof on the east side, the south east side, the ladder line will come down the side of the house, I'm not sure how it will work because of the length, but under the eaves keeping it away from metal, (that part I remember well from advice I was given) to the MJF window thru.

The yard and surrounding area has very tall trees, maybe 110 ft, mostly oaks and other deciduous trees. When I was a kid, all that mean to me was they "rained" leaves all year long and my dad wanted the leaves raked up every week, so I hated them, except to climb them.

But now I wish I had a few more in the right places in the yard. But there are some smaller ones, I wonder if I get it up about 30 or 35 feet will that be high enough?

thanks
steve

21529. Re: [ham-antennas] Coax for Loop antennas V factor etc

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-24 13:08:59 UTC
From: doug pfaff
Topic: 21494 Message: 21529

hi sigi

Using the braid from coax for a ground connection would definatly negate the .66 factor when used as a coax feed line as commented by Richard.

VF factor is likely brand and cable type specific I looked up RG58U coax CU1117 for example from Carol Cable made in North America and its velocity factor is in fact .66 refer to the attached pdf file.

If you check other specific cable type WITH IN THE SPEC SHEET you can find .72 and .82 VF coaxes based on this single page reference.

Can you comment on the European spec sheets

This says we have to be careful on generalizations and get the exact specifics based on specific manufactures product number .

The last coax I used was the c1117 which most electrical/electronic wholesalers stock as its cheap.

I based my design impedance matching section length based on the actual coax using the 1/4 formula using the .66 factor and the matching was 100/50 ohm transition

Can you mention the specific brand you looked up with the manufacturing standards used, I suspect the European standards might be quite a bit higher vf factors to eliminate rfi due to high density systems.in Europe .82 might be consider unacceptable.

Europeans have a much higher populations in smaller spaces and closer physical properties between building etc and closeness to the cable distribution structures.
Newer North American areas are likely buried from day 1 of the construction phase if the physical environment allows eg not mountainous terrain for example areal cable is the only option for this terrain where cable shields factors are important.

Most of our older in house distributions are .66 vf but with the increased electronics environment the interference factor today are much more severe as a result.
what did the Europeans use 20 years ago in comparison

I didn't see what band you were thinking of, or whether you where thinking of a long wire loop or a
magnetic loop.
RG174 is not strong enough to support its own weight on an long unsupported run.
If you where considering a magnetic loop, for the lower bands the diameter of the conductor starts to
become very important.
If that was your intention to build a mag loop, find one of the Hams with large VHF/UHF arrays and
enquire if the know of any water damaged 1/2" heliax/hardline. These guys have normally got their ears
to the ground where there are sources of 1/2" hard line.
The reason I say water damaged is that PTFE foam coax is pretty useless once water gets in, and is most
times thrown out. Cell phone sites will have regular maintenance, which sometimes makes some available.

It makes great low band mag loops ,bends easily into shape and you can join it with low cost 1/2"
plumbing fittings, you only use the outer corrugated braid, so water damage doesn't matter.
I use a 16' dia mag loop made from LDF4-50 on 80 mtrs and 160 mtrs, and requires minimal mechanical
support.
Now I've probably confused the hell outa you all.

From: doug pfaff
Topic: 20501 Message: 21530

If you check a square loop design antenna it will likely be flat across the band but not necessarily 1:1.

The loop formula 1005/freq MHz so length varies allows for any frequency.

I don't have the yard real estate to try anything bigger than 20 design due to city lot size

I cut mine for bottom end at 14.0 MHz but works to 14.350 based on Canadian band plan

I have not done the delta design using cap and sliding rod matching system and a shorting clamp across to the driven element

Have you done a SWR profile on the 80 M band.

Remember the SWR could be either a low number of ohm at 25 or a high at 100 ohms either value give you a 2:1 SWR ratio.

REMEMBER ALSO THE OTHER FORMULA IS BASED ON FORWARD AND REFLECTED POWER LEVELS IF YOU USE A WATTMETER IN LINE

FOR POWER REMEMBER THE P=E/I FORMULA OR P=E SQRD /R.

Do you know the impedance values instead of the swr numbers

Ideally you want to get a 450 value into the antenna for max power transfer then transform it back to 50 ohms to satisfy the transmitter using a balun to go from 450 to 50.

I believe a 4:1 balun leave you at 125 ohms at tx if you have an input impedance of 450 ohms ZO for ladder feed line.

I don't use ladder line due to rfi into shack

You will have to custom wind a 9:1 for the transmitter end.

See Jerry Sevick Transmission Line Transformers available thru ARRL bookstore note he is now a SK ham and other have carried on his work

I have found swr varies with power level due to linearity issue with the diodes in most swr meters even if you match them using a ohm meter.

I saw good information based on a vna analyzer giving you all antenna factor but cost was about 500 dollars

Subject: RE: AW: [ham-antennas] How should I interpret swr data from my loop antenna

I take my measurements at the feed point of the loop. It is a delta. Mine is a 80M size, then tweaked to a 1:1 SWR in the middle of the 20M phone band and I use it 40 thru 10m.

I am surprised you are not resonate and 1:1 somewhere. Do you need a 4:1 balun?

I use a 4:1 duel rod current balun at the apex and RG-8 type to the rig

You might want to try a switchable 1:1/4:1 balun, that is what I use on my 135ft dipole that is feed with 450 ohm ladder line and different bands come in better at different balun settings.

Just thinking and still confused, Rich , Kd0zz

21531. RE: [ham-antennas] my first antenna

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-24 13:45:54 UTC
From: Richard Schmuke
Topic: 21528 Message: 21531

Steve, I would love to trade you some 100ft red oaks for some blackjack oaks and scrub cedars. My loop works great and the feed point is about 40ft on a homemade steel tilt over, the rest of it is 25 to 30ft because of the lack of tall trees close by. Still it is the best, in general, I have ever used next to a beam.

Rich, Kd0zz

Subject: [ham-antennas] my first antenna

Well I don't have it yet,

but I ordered a "store bought" 160 meter loop with 124 ft ladder line

the house has a tall roof, I used to climb trees when I was old enough to reach the lowest limb, perhaps 5 years old and later I was an Ironworker, and even if I shouldn't, because I have back and neck problems I climbed up onto the roof.
I was still scared, which showed my brain was working just fine.
I don't know if I'm up to putting the antenna up myself or not.

The top of the roof must be 30 or 35 ft high, there are several trees in the back yard that are possibly useful, but aren't very big trees. The wire is 14 ga with insulation, so it's probably on the heavy side.

If I only hung it from 4 points, I'd have to have strong trees or if I am able to use the top of the roof as two points for the front.

Maybe I can put more insulators, I might go over the top of the garage, and that would be an additional insulator and maybe if I added several more so there wouldn't be so much weight on the one in the back yard all the way in the back, north west side.

Then over to the other side of the back yard, or the north east corner, I'm not sure which tree, but there is a large red oak tree, and from there I'm not sure. When I first measured off the yard, it's roughly 120 ft x 110 ft, so I may have more antenna that yard, unless I spread it or fold it a bit, I'm told I can do that.

It's interesting, I get all sorts of advice from knowledgeable people, and I understand, (most of the time) what they are talking about, but when I go to talking about what they advised me to do, I can't say it very well.

Anyway, from the top of roof on the east side, the south east side, the ladder line will come down the side of the house, I'm not sure how it will work because of the length, but under the eaves keeping it away from metal, (that part I remember well from advice I was given) to the MJF window thru.

The yard and surrounding area has very tall trees, maybe 110 ft, mostly oaks and other deciduous trees. When I was a kid, all that mean to me was they "rained" leaves all year long and my dad wanted the leaves raked up every week, so I hated them, except to climb them.

But now I wish I had a few more in the right places in the yard. But there are some smaller ones, I wonder if I get it up about 30 or 35 feet will that be high enough?

thanks
steve

21532. Question about building 160M horizontal loop

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-24 14:06:12 UTC
From: Jon
Topic: 21532 Message: 21532

I am about to finally erect a 160M loop. It will be as high as I can get it and as near to being square as I can get it. It will be made out of 18ga stranded and insulated copper fed with 450ohn ladder line. I'm not sure if I will put a balun ad the outside wall of the shack and rg8 on in to the tuner or run it on in to the tuner. My calculations say it should be 515'. The question comes from various pieces of "advice" vary. It will be used as a multi band antenna. I thought it should be the calculated length to work better with all bands but I've been told it makes no difference. Why I'm asking is my piece of wire is 560' and I could manage to get it all up and before I cut it would like to hear from those that KNOW from use and are willing to share the information.

Thanks for the help

21533. Loop Skywire

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-24 14:57:11 UTC
From: wa6txu
Topic: 21533 Message: 21533

Has anyone had any experience with the "Loop Skywire"? I have seen it in the ARRL Antenna project book. Looks very interesting, and does not seem to be too difficult, nor expensive to build, and appears to do well at 40 feet with 65 foot sides (for the 80 meter model). I have the space and the wire, and currently have a "V" wire beam. Dave.

21534. RE: [ham-antennas] Loop Skywire

Date: 2011-12-24 15:36:05 UTC
From: Richard Schmuke
Topic: 21533 Message: 21534

The ARRL has had it in its books for years, the first was direct fed with 50ohm coax and the later had a 72 ohm coax transformer. I put one up with the matching section and it worked fine but was only for one band, 40m at the time because of the coax transformer. I changed mine then to a multi band by installing a 4:1 balun at the feed point. Now it is 80M size, delta shaped, feed with coax and does great on all bands 40 thru 10.

Rich, Kd0zz

From: Ed Stewart
Topic: 21535 Message: 21535

I have a 1/2 inch copper tubing J-Pole antenna question. Which way would be the best way to route the coax from the connection to the J-Pole, use a 90 degree coax connector and run the coax down the support tied flat or use a straight connector on the coax and make the coax loop down to passed the short bottom stub of the J-Pole. I would like to use the 90 degree because it is more secure tied flush to the pvc support , but don't know whether the coax running flush will efect the antenna's swr or performace. Ed-KB3WRX

Thanks Rich. As a delta rather than a square, I assume the sides are 87 ft long rather than.the 65 ft for a square pattern. How high did you put it? Better to put the balun at feed point rather than at the tuner (and then feeding the ant with open line)?

21538. RE: [ham-antennas] Loop Skywire

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-24 17:13:45 UTC
From: Richard Schmuke
Topic: 21533 Message: 21538

Dave I did not measure the sides. It is a delta shape with rope running at the corners out to available trees. Here is how I made it. I put up a 80M size delta loop. I feed it with coax and have a 4:1 balun at the apex. The apex is about 40ft and the other two points are about 25ft. I used pulleys and rope at all points for quick adjustment. It is spliced in the middle with a split bolt. A 80m loop is a 100 ohm antenna but when operated on a multiple frequency it is a 200 ohm antenna so a 4:1 balun matches it to 50 ohm coax. I checked it at the area of the 20M phone band where I work and adjusted it to a 1:1 SWR. I now can work 40, 20, 17 , 15 , 12 and 10 on one antenna. The low SWR point on 17 is a little low in frequency but all other bands are great. 17 is fine with a inboard tuner if you have one. If you try this remember if you are adjusting for a good SWR setting on 20 and are inclined to use math to figure the length needed for adjustment that you will be adjusting a 80M antenna so if you think you need 4 inches of trim by ciphering it will be 16 in the real world.

I use it as a multi-band loop that does not need a external tuner that is the reason for the balun at the apex and coax.

I also have a 135ft doublet that is fed with ladder line and a balun just inside my window pass thru. With a short run of coax to my tuner. The balun for the doublet is one that is switchable from a 1:1 or a 4:1 depending on what band requires what balun. The doublet ends are east and west, this allows me to A/B switch instantly between the two different antenna setups to see which one is working for that direction. A couple of weeks ago during the 10M contest the doublet had gain into Europe, Japan and the pacific , next weekend was the RAC and the loop was better into Canada, because the higher bands have loops of the end. If I had be on 80 or 40 the doublet would have been better. I know I could add another switch and run both as ladder line but then I would have to move out of my chair to change antennas and I am old and lazy.

Next question???

Rich ,KDØZZ , ☺

Thanks Rich. As a delta rather than a square, I assume the sides are 87 ft long rather than.the 65 ft for a square pattern. How high did you put it? Better to put the balun at feed point rather than at the tuner (and then feeding the ant with open line)?

That would be better than what I have , the only tall trees are farther into the woods on my land and the land runs down hill so the wire would be thru the trees. A 50ft pine would be better than my cedars and scrub oak that I have close by. Rich

you can have my 50 ft. pine .

Rich, you have sold me on the coax and the balun at the feed point. Sounds good. Thanks.

Sent from my awesome iPhone 4S

On Dec 24, 2011, at 12:13 PM, "Richard Schmuke" <rdj@...> wrote:

> Dave I did not measure the sides. It is a delta shape with rope running at the corners out to available trees. Here is how I made it. I put up a 80M size delta loop. I feed it with coax and have a 4:1 balun at the apex. The apex is about 40ft and the other two points are about 25ft. I used pulleys and rope at all points for quick adjustment. It is spliced in the middle with a split bolt. A 80m loop is a 100 ohm antenna but when operated on a multiple frequency it is a 200 ohm antenna so a 4:1 balun matches it to 50 ohm coax. I checked it at the area of the 20M phone band where I work and adjusted it to a 1:1 SWR. I now can work 40, 20, 17 , 15 , 12 and 10 on one antenna. The low SWR point on 17 is a little low in frequency but all other bands are great. 17 is fine with a inboard tuner if you have one. If you try this remember if you are adjusting for a good SWR setting on 20 and are inclined to use math to figure the length needed for adjustment that you will be adjusting a 80M antenna so if you think you need 4 inches of trim by ciphering it will be 16 in the real world.
>
> I use it as a multi-band loop that does not need a external tuner that is the reason for the balun at the apex and coax.
>
> I also have a 135ft doublet that is fed with ladder line and a balun just inside my window pass thru. With a short run of coax to my tuner. The balun for the doublet is one that is switchable from a 1:1 or a 4:1 depending on what band requires what balun. The doublet ends are east and west, this allows me to A/B switch instantly between the two different antenna setups to see which one is working for that direction. A couple of weeks ago during the 10M contest the doublet had gain into Europe, Japan and the pacific , next weekend was the RAC and the loop was better into Canada, because the higher bands have loops of the end. If I had be on 80 or 40 the doublet would have been better. I know I could add another switch and run both as ladder line but then I would have to move out of my chair to change antennas and I am old and lazy.

21541. Re: [ham-antennas] J-Pole question

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-24 18:42:14 UTC
From: Todd F. Carney
Topic: 21535 Message: 21541

*Well, most j-poles need a loop balun up there---three or four turns of the coax---to match the impedances. Take a look as some pictures of j-poles online. You'll notice the balun right there at the bottom and secured just under the horizontal member of the J. It just may be better to hard wire the balun to the feed points, and attach your connector at the end of the balun. For that, a straight connector may be best.

Try this shortened link to a Google search page showing images of various j-pole arrangements. Lots of good ideas on securing the coax to the mast as well.

http://bit.ly/tyGAh2

Happy Holidays!

I apologize that it's taken so long to reply on this subject...it's a busy time...

Anyway, I've only seen one reply that remotely addresses my concern with your question...and, that's the one referring to 'skin effect'...

My concern is simply, any antenna that uses any material of higher electrical resistance than the usual copper or aluminum will start to dissipate more and more power in heat rather than electrical and magnetic radiation.

Larsen Antennas used to coat their stainless steel whips with a low resistance material to counter that very effect...
As many may remember, that was a very successful antenna..

Combine electrical resistance AND 'skin effect' and you may have a snow-balling effect.

My 80m delta is only about 25' and droops low. Its odd but those putting up 160 loops seem to have to get them higher to work. One thing to keep in mind is your target band if you have one. Target band for a 160 loop for me would be 40m. They are a good multi band antenna especially with ladder line but a 160 loop on 160 will radiate mostly straight up. On 80 nearly the same but Don is reporting some good results at 2w/l. I don't use mine much at 2w/l. On 40 it will be a good compromise at 4w/l. A pretty good cloverleaf pattern and approximate 35 degree radiation angle at 20 foot height and about 20 degrees at 50 feet high. After 4w/l the pattern goes from a cloverleaf to a multi fingered looking pattern like your hand.
I think everyone should try one sooner rather than later. Mine seems to be very broadbanded also so very little retuning necessary within same band.

###Todd , what a great site for J-Pole information. I agree with you about a coax choke. I attach the RG-8X coax with small hose clamps and then solder in place, let the coax drop down thru the center, add a ty-wrap at the horizontal part between the verticals, then a few turns of coax around the support to form the choke. Next I add a SO-239 single hole with a hood. I then can attach RG-8 size coax down to the rig.

I don't think zinc is that bad of a conductor. (steel electric fence wire is galvanized)

And when the copper coating was blasted off by flying bug teeth, (eyes, wings, legs etc.) they
just quit working, nonsense.

> Combine electrical resistance AND 'skin effect' and you may have a snow-balling effect.

Stainless steel wire and rod antennas work undetectabley the same as anything else.

The 12 1/2 gage high tensile wire is good for what it is made for. If you want to run a single wire over a very long distance it will work. It is very springy , more so than copper weld. It needs to be crimped and if you bend it, it will develop stress cracks. Normal steel is about 55Ksi in strength, this is right at 200Ksi, much stronger than normal steel wire, harder, stiffer , it is made for spring loaded farm fencing.
Rich ,KDØZZ , ☺

from the middle of Missouri , out in the sticks with the hicks and the ticks.

Also found this 12 1/2 Gage High Tensile wire on the Tractor Supply site
4000' for $99.99 http://preview.tinyurl.com/7fj4n8s
Also your pricing varies by store location.

I agree with Dave, point the antenna straight up and see if you can get
your SWR under control. Also, while it is a little difficult to read, you
might download the TH-4 manual from BAMA at the following address:
http://bama.edebris.com/manuals/hygain/th4-190/
I'm not sure what the "190" is all about, but the basic information should
be of some help in putting the antenna together. Actually, your message is
a little confusing. At one place you say that you got the TH-4 manual and

at another you suggest that it is something else.

Hi,

Happy Holidays and Merry Christmas to all.

Recently installed on the roof of a Hustler 5 BTV planning to change my antenna G5RV jr. Install two radials for each band, leaving an average of 1.5 swr at the center of each band.

But initial tests it seems that the antenna is deaf because they do not get to hear more distant stations, Argentina, Chile and USA in bands like 10m, 20m or 40m. With the G5RV jr. average having 4.5 swr on the bands and helped with an antenna tuner stations copied new zealand, region 1, Bosnia, Greece, Russia, Asia, etc..

This is normal for this type of antenna or do I have some component of BTV with the problem.

Thanks for the help I can provide.

Severino - YV5OF

Depending on the height of the G5RV I would expect the two antennas to
be within an S-unit of each other

one better on some signals the other slightly better on others.

My first suspect is the feed line to the 5BTV

Severino,
What did you measure SWR with? Low SWR doesn't mean
THAT'S where your antenna is resonant. IF you have access to an
antenna meter, at what frequency is your feed point impedance at
between 33 and 50 ohms? The closer to 33 ohms, the better your
radial system is for THAT band. How are you feeding your antenna?
Coax? Open line to a balun to coax? or Coax to balun to antenna?
Any type of RF choke at bottom of the vertical? (to prevent RF on the
coax shield?
Need a little more info to help you out.
FYI- I have been using 4BTV, 5BTV, and 6BTV for almost 34 years.
So I have some knowledge about them. (And the sometimes heart-
ache of tunning them.)
Let me know..on or off list. I have a ton of notes I can scan and send you.

Of course they radiate, as they SHOULD.

#1, they have a LOT larger conductor and probably 1000x the surface area so the percentage lost is lower than it would be with a wire antenna.

#2, the cost of putting up a copper tower of sufficient strength would horrendously more expensive, probably in the millions of dollars. OTOH, we are talking about only $15 more for copper wire than for galvanized.

YMMV but I would not use galvanized wire to save $10 or $15.

Do you use surplus RG-58 to save a couple of bucks too?

Many Thank´s for replay Dave,

1-. I use MFJ-229b Analyzer

For 10m Point High SWR 1.6 - 28.000 / Point Low SWR 28.570 1.1
For 15m Point High SWR 3.2 - 21.900 / Point Low SWR 21.300 1.0
For 20m Point High SWR 4.3 - 14.900 / Point Low SWR 14.300 1.2
For 40m all range 7.000 - 7.200 SWR 2.0 Average
For 80m range 3.560 - 3.670 SWR 1.8 Average

2-. I use for feeding LMR-200 same G5RV.

3-. Balum is Air Choke (Coaxial RG-8) Homemade. / Balum was on recommendation, but is i can remove it.

4-. Radial Cable #14

Severino
The 10 meter SWR looks good.
The 15 meter SWR looks bad
The other bands not too good also.

On the BTV and all other trap verticals. the antenna must be adjusted starting with 10 meters, then 15 meters, then 20 meters etc etc.
Each lower band depends on the previous band to be adjusted correctly. So, if 15 meters is bad then 20 meters will be bad and 40 will be bad and so on.

So, you need to adjust the 15 meter band according to your manual.
Then adjust the 20 meter band after the 15 meter band looks correct.

Best Regards

From: Stan Labinsky Jr.
Topic: 21535 Message: 21565

I recently came across an old article in QST, where a ham/commercial radio guy commented the he was loosing about a dB in the right angle adapter. He suggested using right angle Pl259 type connectors in any situation that demanded a right angle connection.

But, I'd even suggest staying away from attaching an SO238/PL259 to your antenna. The reason is that the PL259 connectors are NOT weather/water proof and water in the coax's shield will eventually create headaches, specifically the loss of the shielding function in the affected piece of cable with an attendant increase in loss. I've seen at least a ten foot run of ruined cable in a 2-way installation I recently had to repair... water dripping out of the connector at the radio end.

You'd do just as well as was suggested connecting the cable directly to the antenna but, you want to thoroughly seal the exposed shield and center conductor after making your attachment. Use a sealant that DOES NOT smell like vinegar as it cures. Vinegar, dilute acetic acid is corrosive to copper and will result in failed connections... seen those warnings many times, usually from folks who have been bitten.

Otherwise... have fun!

Stan

Topic: 21535 Message: 21567

>>Use a sealant that DOES NOT smell like vinegar as it cures. Vinegar, dilute acetic acid is corrosive to copper and will result in >>failed connections...

Thanks, Stan! I've never heard that about acetic acid and copper. So I just did a quick Googling to confirm my suspicions: As far as I could tell, all silicone caulks, sealants, adhesives, etc. are moisture-curing, acetic acid types. Even the kind for aquariums. Gee, I've always thought of acetic acid as sort of benign. I used to have my hands deep into it in the darkroom: it's used for stop bath to neutralize the alkaline developer.

*So . . . . . the big question now is: what would be the best sealant to use for weather-proof electrical connections? How about roofing tar? A latex-type caulk? Layers of painted-on Dip-It tool handle plastic?

Don't anyone bother suggesting electrical tape! It falls off in the sun and leaves a very sticky mess behind. I hate the crap. Alright . . . okay, I use it once in a while for various purposes as it does sometimes fill-in for a better choice when one is not at hand. But, hey . . . we all have to be flexible, right?

Yes, they can be painted with no effect on the SWR or anything.

I coated my Antron 99 last Summer with a Clear Polyurethane.

IF you live on a disability income like many of us do you might damn well
"use surplus RG-58 to save a couple of bucks "!!!
try living on about $1000 a month and see if you are singing the same tune.
Back in my hole.
BTW: I sign my messages why don't you?

*In boat building, the rule is to always paint any fiberglass exposed to the sun. The issue is with UV. This is a great deal more important if the laminating resin used is epoxy than it is with polyester. There are UV-absorbing clear varnishes or urethanes, though you may need to look toward boat materials suppliers to find. Varathane may have a UV-blocking varnish at Home Despot or Blowes.

I like to paint my stuff flat black. You know, like the stealth bomber. I use good-ol' Rustolium, but I paint it on rather than spray it. I finally got tired of the expensive cans, half of which either blows in the direction opposite my workpiece, and a quarter of which blows straight up my nose. Only a quarter gets on the piece. So I tried their canned paint and I love it. I use a foam brush for a smooth finish, and flat shows little in the way of brush marks anyway. I bought a little 8-oz can and I've painted several masts and j-poles with it, three coats usually. I still have about half left.

*Adrian,

Merry Christmas!

You stay up late like I do. I hope I didn't offend you. But I thought of
that old joke about the woman who fed her husband dog food to save money.
She told her friend about it who was then shocked when the man died. "Do
you think it was the dog food?" the friend asked. "No. He was just laying
in the street licking his nuts and he got run over by a truck."

Happy New Year, too. And happy QSOs as well.

73,

Todd

21574. RE: [ham-antennas] J-Pole question

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-25 08:23:19 UTC
From: jo barden
Topic: 21535 Message: 21574

Hi Todd

the old way was (as far as I know it anyway) cover with Vulcanised India Rubber (VIR) or self amalgamating tape and then pvc insulation tape. the pvc was by way of UV sacrificial to protect the undertape. I asked about "Plasti-dip" a while back and since then I read a bit in "Antennas from the ground up, vol 2" that Cebik also used Plasti-dip so you may want to consider this.

My own view is to annually check antennas and feedlines as part of the station maintenance. I do this for my HF antennas but my VHF/UHF WatsonW- 2000 is a bit awkward to get at so it is left alone (bad practice I know).

there are some aquarium sealants without acetic acid as I had to get some to repair our Axolotl tank, it takes a little longer to go "off" though. I would look for exotic/reptile shops for it. Well here in the UK they are exotic.

Enjoy your turkey.

Jon

From: Adrian Flynn
Topic: 21480 Message: 21575

Todd,
Didn't offend me at all.
I have had things trrown at me all my life as I am FAT to start
with and I just reply to them basicly with a "Walk in my shoes for a mile"
type comment.
I have had to really learn to pull my horns in and reause since I went
disabled about 14 years ago.
It was a *major shock* to go from taking home $1,500 a week to living on
$850 a month!!!
That was after using my retirement to live on for 3 years while fighting
the
Government for my disability, I was turned down as being fit for work when
I couldn't walk across a room or stay awake more than 20 to 30 minutes at
a time due to lack of oxygen.
My lungs were toast from Asthma, smoking and the final straw was inhaling
LIME DUST for 17 hours on the job one day. Employer provided no filter
mask or any thing while I was driving my truck in a 3/4 mile circle hauling
re dried lime from the hotplant to the grizzly to re stack it.
(The man dumping my truck didn't have a mask either and he had blood
coming out of his nose in about 7 hours and was spitting up blood before
the end of the day, I never say him again & I would not be surprised if he
died later that night!)
I had my windows closed and AC set to recirculate but at end of 17 hours
I had a layer of lime dust 2 inches deep on everything in the truck.
I used a 1 1/2 inch fire hose to clean it out and still had dust showing up
to
be re cleaned for a week.

I hope I didn't offend you with my reply but it falls in line with my
"Walk a mile in my shoes", I have walked many miles in my old shoes and I
wish I could do it today, you have a Merry Christmas and enjoy your family
to the Max!

From: Richard Schmuke
Topic: 21535 Message: 21576

Check out DAP Silicone Plus,(thanks to K5EST) it is what you are looking
for. You can also get it in a small tube, black , with auto parts but the
auto parts is more expensive for a smaller tube.
Rich , Kd0zz

Thanks, Stan! I've never heard that about acetic acid and copper. So I
just did a quick Googling to confirm my suspicions: As far as I could tell,
all
silicone caulks, sealants, adhesives, etc. are moisture-curing, acetic acid
types. Even the kind for aquariums. Gee, I've always thought of acetic acid
as sort of benign. I used to have my hands deep into it in the darkroom:
it's used for stop bath to neutralize the alkaline developer.*

*So . . . . . the big question now is: what would be the best sealant to
use for weather-proof electrical connections? How about roofing tar? A
latex-type caulk? Layers of painted-on Dip-It tool handle plastic?

Don't anyone bother suggesting electrical tape! It falls off in the sun and
leaves a very sticky mess behind. I hate the crap. Alright . . . okay, I
use it once in a while for various purposes as it does sometimes fill-in
for a better choice when one is not at hand. But, hey . . . we all have to
be flexible, right?

Dave thanks for the info,

I will work this week to adjust the antenna. These adjustments should improve the SWR, and also help improve the reception?

Did you reply to me , Dan ?
If yes, well, proper adjustments of each band segment starting at the highest frequency (10 meters) and then the next band , 15 and then the next 20 and so on, will certainly improve the SWR and therefore the efficiency . I assume that you have at least 20 to 30 radials on the ground. You must install the radials FIRST !!!

I do not know if it will make a large improvement in receiving since receiving really depends on the propagation. Propagation changes all the time.

But, before you can worry about receiving, you need to make sure that the antenna is installed and adjusted properly. Please look at this article from DX Engineering.
http://www.dxengineering.com/pdf/BTV-INSTALL-GUIDE-Rev0b.pdf

If you follow this article, you will surely have a well working antenna.

Severino --

Dan's info is solid. I have a 4BTV with the 17M & 30M kits over 36 radials, on the ground. While trap verticals are a compromise, you should still be able to get very good performance on all bands.

Insuring that your radials are cut properly is a big part of it; it might be helpful to add a couple of radials per band.

With careful tuning, per the instructions from DX Engineering, this antenna can be a good performer.

21581. G800SA Yaesu rotor control unit

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-25 15:50:45 UTC
From: Dave
Topic: 21581 Message: 21581

I have an 11 month old G800SA rotor. After 6 months in operation, it suddenly stopped working. When I put my ear on the cabinet of the controller, I could hear a faint hum. No light, no action when operating the rocker switch. I have another, identical 5 year old rotor. I used it to make sure the problem was not the rotor itself , or the cable.

Sent to to Yaesu in CA said they couldn't get the part to fix it. When they sent it back it has a very loud hum when plugged in, even with switch in off position.

I'm looking for a replacement controller unit or suggestions or who might be able to fix mine.

Sorry for the lengthy post.

Thanks NB5B

That is absolutely pitiful that the "Yaesu repair station" couldn't fix a Yaesu product that is
under a year old, and I am a Yaesu loving man.

> I'm looking for a replacement controller unit or suggestions or who might be able to fix mine.

Look for a friendly local repair HAM that is willing give you a hand, baring that look for a
local TV/radio/everything electronic repair store, preferably one that run by a HAM, pay him what he
his time and training is worth.

Jon,

Get it up in the air and check it out for SWR and so on, before you cut the wire. I wound up adding more wire to make mine work so there are multiple splices in my system. I would think it would be nice to know where you are at before you make adjustments.

Merry Christmas

Jon

Try using your tower with a wire stood off the tower and a base load coil.one of the older hams who had lots of money and time to build things you need a good tuner as it still a very short antenna for broadcast band frequencies.

Look at the AM broadcast towers in your area believe there a quarter wave length and your much less shorter than that.

You must have a hugh piece of real estate and lot of supporting structures to tie it too.

Remember proximity to ground and suppoet structures to support it will make a impact on thefinal reading.

My loop was to close to the ground situation like 3 metres max or grounded infrastructures it made a difference of over two feet on the calculation for the lowend of the band on 20 m.

As other have comment it hears things that a dipole vertical or other wire antenna can't.

So remember to take actual readings and make actual adjustments for your site conditions and not rely on the textbook diagrams etc my exterior finish of stuco has an effect on design length

You don't ever have to cut your wire. I cut each half of a 40 meter dipole about 6 feet too long
and I fold the high Voltage ends back through the end insulator and secure it with a small "split
bolt," an electrical fitting. It doesn't matter whether the wire is insulated or bare.
(folded back wire cancels the wire folded over)

Adrian, if you follow any of my posts or have seen my photobucket you would also get the idea I am on a fixed income that is why I try to make as much as I can . I understand working with what you have on hand. I am lucky I have most of my fingers and can still do some things.
I also understand how employers in the past did not protect their people as many due today but there was not things like MSDS like there are today. Back when I built model airplanes for a living the cutting fluid in the machines was bad for you , then when it came off the machine you took it to the vapor degreaser and got the fumes from the tri-clor in your lungs. Next step was to solder pressure test sensors into the stainless steel with fumes coming up from the acid flux. If you made a mistake you could braze in a patch and sniff the cadmium fumes from the rods they used then. Later I moved to the other end of the test lab and did fatigue and static testing. We cleaned the skins with a strong solvent that was latter outlawed but we continued to get it under a chemical mix combination to get it shipped to us. We had every solvent you could think of in 55 gal drums. All testing was also counterbalanced by several thousand pounds of lead. We made up our own lead weights until the last 10 years. I sure miss the good old days. Gee you wonder why I got cancer in my throat and neck.
Rich , Kd0zz

Todd,
Didn't offend me at all.
I have had things trrown at me all my life as I am FAT to start with and I just reply to them basicly with a "Walk in my shoes for a mile" type comment.
I have had to really learn to pull my horns in and reause since I went disabled about 14 years ago.
It was a *major shock* to go from taking home $1,500 a week to living on $850 a month!!!
That was after using my retirement to live on for 3 years while fighting the
Government for my disability, I was turned down as being fit for work when I couldn't walk across a room or stay awake more than 20 to 30 minutes at a time due to lack of oxygen.
My lungs were toast from Asthma, smoking and the final straw was inhaling LIME DUST for 17 hours on the job one day. Employer provided no filter mask or any thing while I was driving my truck in a 3/4 mile circle hauling re dried lime from the hotplant to the grizzly to re stack it.
(The man dumping my truck didn't have a mask either and he had blood coming out of his nose in about 7 hours and was spitting up blood before the end of the day, I never say him again & I would not be surprised if he died later that night!)
I had my windows closed and AC set to recirculate but at end of 17 hours

I had a layer of lime dust 2 inches deep on everything in the truck.
I used a 1 1/2 inch fire hose to clean it out and still had dust showing up
to
be re cleaned for a week.

I hope I didn't offend you with my reply but it falls in line with my
"Walk a mile in my shoes", I have walked many miles in my old shoes and I
wish I could do it today, you have a Merry Christmas and enjoy your family
to the Max!

Well.....

Instead of kicking a opinions around, why not just model a dipole using copper wire and then compare it models using different types of wire.

If I remember correctly, it doesn't make as much a difference as you'd think it should.

Any antenna radiates better than no antenna.....

> (folded back wire cancels the wire folded over)

I will disagree that it doesn't matter whether the wire is insulated or bare. If it is insulated, then you still have the long electrical length, just the radiation is cancelled by the looped back wire. If you are running high power, it's also possible (but I admit unlikely) that there would be enough voltage difference to arc through the insulation, especially if compressed with the split nut. If that happens, you will get unstable results and probably RFI from the arcing. Sometimes the ends of antennas with high power will have corona discharges. That would not be a good situation with insulated wire bent back onto itself.

I agree on a dipole not to cut the wire but just bend it back but it's best to use bare wire in this situation. However, the OP's topic was for a LOOP antenna and it would be more difficult to do in that environment.

Subject: [ham-antennas] G800SA Yaesu rotor control unit

I have an 11 month old G800SA rotor. After 6 months in operation, it suddenly stopped working. When I put my ear on the cabinet of the controller, I could hear a faint hum. No light, no action when operating the rocker switch. I have another, identical 5 year old rotor. I used it to make sure the problem was not the rotor itself , or the cable.

Sent to to Yaesu in CA said they couldn't get the part to fix it. When they sent it back it has a very loud hum when plugged in, even with switch in off position.

I'm looking for a replacement controller unit or suggestions or who might be able to fix mine.

Sorry for the lengthy post.

Thanks NB5B

21593. Re: [ham-antennas] J-Pole question

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-25 21:21:47 UTC
From: Stan Labinsky Jr.
Topic: 21535 Message: 21593

Well, Todd, the stuff I've been using is DAP Indoor / Outdoor Sealant.
Usually you can smell the vinegar right out of the tube, this stuff's
odorless... so.
But, I'll have to check back on the last repair I did (I do some 2-way radio
work on schoolbusses and the yard managers are increasingly demanding that
the larger antennas, the lo-band guys be side mounted for mechanical
protection) to see how it turned out.

When mounted this way the bottom side of the Motorola mount is exposed to
the weather and sealing the coax is a must or you'll loose the cable.
Actually, water can get into the antenna's coil too, so the bottom side of
the whole mount has to be flooded to keep the water out.
And, to those who use this mounting scheme, you can loose the "O"ring, it
does nothing for you and actually makes it a bit harder to tighten the
mount.

Stan

*Good suggestion, Stan. I just checked the DAP site. Their Indoor/Outdoor sealant is a paintable acrylic latex. They also have some polyurethane sealants that should work well, too. I imagine any latex or poly sealant would work fine. Of course anyone could come back with: "I wouldn't use that stuff if I were you. It contains monkey urine and it might change the electrical length of your antenna. . . ."

I agree with and totally understand "have most of my fingers and can still
do some things".
It was a real challenge for about 4 years to find out I could no longer
run, carry heavy loads,
try to work at something for more than a few minutes.
I also had to resort to driving at night as if I entered a section with
trees the light flashing
through the trees would put me to sleep in less than 5 minutes! This kept
on until I finally
got Oxygen after having a case of "Congestive Heart Failure" when they put
me on O2 for
24/365 the rest of my life.

> *I also understand how employers in the past did not protect their people
> as
> many due today but there was not things like MSDS like there are today.*
>

I agree with old employers not protecting employees, we were disposable
cattle to them.
But there were MSDS on the lime at the time this happened and had been for
several years,
just a case of penny pinching and YOU having to CYA!

I sure miss the good old days. Gee you
wonder why I got cancer in my throat and neck.
Rich , Kd0zz

Yes the good old days of rosin fumes from soldering day in day out repairing
consumer electronics, and like you did breathing in all of the unknown

chemical
sprays & washes used for repairs.
I have no idea what was in all of them but one I do remember as it was
mixed
by the shop foreman was a mix of Kerosene and Acetone with a couple of
other items!
We all have to carry our loads but it seems many time we are a very small
minority
and others think everyone should just run out and "Buy" the "Best" out there
as "Everyone is made of money like they are or say they are"/

Off my soap box for the rest of this year, I am going to rest up and try to
relax
so I will have a good attitude when I go in for 6 hours of surgery Jan 31,
with at least 2
weeks recovery time in the hospital.

Hope you and your family had a great Christmas we sure did.

All I have ever used for the last 25 years is a product called coax seal. Gooey black thick tape like product that can be stretched, molded and formed to any shape you want. After some time it develops a dry firm outer shell and can be removed easily by making a slit and just rolling it back. Won't even stick to your fingers. Heating and cooling tech's have it as a wrap on insulation on the return refrigerant line. Nothing better.

21597. Re: [ham-antennas] Question about building 160M horizontal loop

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-26 00:58:58 UTC
From: Jon Ermels
Topic: 21532 Message: 21597

Don, thanks for the advice. I've always made my wire antennas a little long for tuning but I was talking about waaaaaaay long, like 55' or even hundreds of feet longer and leaving it without any SWR testing. their reasoning was the more the merrier and I'm going to be using a tuner anyway. I figured the moreI had to rely on the tuner, the more power I wasted in it. Also I figured it would also make the higher bands harder to tune also.

It will be made out of 18ga stranded and insulated copper fed with 450ohn ladder line. I'm not sure if I will put a balun ad the outside wall of the shack and rg8 on in to the tuner or run it on in to the tuner. My calculations say it should be 515'. The question comes from various pieces of "advice" vary. It will be used as a multi band antenna. I thought it should be the calculated length to work better with all bands but I've been told it makes no difference. Why I'm asking is my piece of wire is 560' and I could manage to get it all up and before I cut it would like to hear from those that KNOW from use and are willing to share the information.

> would I want to leave it there?

I was referring to dipoles and such that are normally "trimmed to length."
I also said 6 feet too long, almost a foot is used at the center balun and barely 4 feet at the
ends. That's 6 feet over the calculated length using 75 Ohm coax.
The tear drop look of the ends theoretically broad-bands the antenna slightly.

Used to work at Missouri Portland Cement Co. as electrician. Know all about lime dust. It causes silicosis then lung cancer. MSHA said it was safe since when you left it would be out of your lungs in 3 days. Oh? What if you work there until you retire. That is what happened to the first retiree, lung cancer. Best thing for antennas is call your local club. Many will be thilled to show up as a group and raise antennas. You must have coffee and doughnuts, though.

Topic: 21480 Message: 21603

I will remember that, I am not going to put up any wire here
as we will be moving in Apr when the lease is up.

Beverage huh?
Now is that the type where the water shoots out the top for an antenna?
LOL
There will be plenty of beverage to go around, last party we emptied 2 bath tubs of beverage.

21605. coffee and donuts ... or a bucket of chicken!

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-26 09:24:47 UTC
From: kj6ddf
Topic: 21605 Message: 21605

I asked the question about the galvanized wire 20/22 ga, and as it happens, I'm also disabled, but I didn't want to start a war! Talking over ideas with a experience amateur who does a lot of experimenting building loop antennas, he mentioned that he had build an antenna once using galvanized steel fence wire, and I wondered if anyone else ever heard of it. But it wasn't a cost cutting measure, I think it was an experiment.
And even if one is very short with their budget due to disability, I think the suggestion about getting help from a local amateur club is an excellent one!
I've had chronic pain for 22 years, was born with a back condition (insert my own ridiculously long probably very boring story) and the best thing I've learned with God's help is to look at what I have, not at what I don't have...

And as it just so happens, I did recently visit a local Amateur club, I was concerned if I'd be able to attend, because I tend to prefer my recliner and two heating pads, but I went and was very glad I went. And as it also just happens, they talked about putting up antennas for others, I didn't ask, it was my visit, but after a few came over to say Hi, and after followed up with emails, and I asked if it were possible to give me some help putting up the loop antenna I ordered. I ordered a "store bought" ready made antenna, because with my disability, a.) wire antennas are inexpensive b.) I'd probably make some stupid mistake c.) I'd end up in a lot of pain trying to build it myself, and that's more costly in doctor visits (copays etc.) than getting it done by the techs at a company.
But I hadn't thought of getting help from the club. I was going to stumble around in the yard, try to shoot a line over branches and probably realize after I threw my neck and back out how over my head I was (Often I'm able to easily "think" a project through, without realizing I can't do what I used to be able to!)
But after going to the club, and I got a mental picture of younger healthier club members who have experience putting up antennas, and most of all, (don't forget the coffee and donuts/ bucket of chicken/ Bar-B-que) the close friendships that will be built in the process!

That's what so wonderful about amateur radio and clubs!

So I would imagine that if someone didn't have the funds necessary, a club would be willing to help.
Sitting there at the meeting, I didn't say anything, I was there to observe. I hear them say over and over, "How can we help out in the community?" "how can we help others?"

they must have said it a dozen times? they set up a committee to look into it! I am sure other clubs also want to help others!

Forgive me for being long winded, just wanted to say, I didn't know how much help was out there, and I often sit in my chair afraid to go anywhere because of the pain I might get into, (I'm in enough pain already sitting on the heating pads) but when I did go the local amateur club, I was so happy. And I hope others who are disabled also find the same help I did. For those not able to get out, I believe local clubs would respond favorably to a request for help, by phone call or email.

anyway,just my 2 cents worth

Steve

21606. UNUN Question on a G Whip Widebander antenna

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-26 11:40:28 UTC
From: oldgoldennuts
Topic: 21606 Message: 21606

I have a G whip Widebander antenna. This is an End-fed with a 17.5 meter radiator and a 20 meter counterpoise. the counterpoise runs to ground after running around the garden floor to a spike. The Radiator runs up to a pole just above the house which is isolated at that point. I must say despite the hype for this company newly reformed that im not impressed with this antenna. That's not to say others might have different expieriences with this specific antenna. So my question.

From what I understand after texting the owner the transformer has neutral terminals.Ie. Either the radiator or the counterpoise can be connected either way on the terminals. Here is what I want to know. This being the case how does the UNUN know which wire is the radiator, or is it looking at both wires as radiators. This been the case then my end-fed would be an osd and the UNUN should be a BALUM.Any help or understanding would Nice. I hope everyone is having a Merry Christmas

Thanking you for any help

Shaun M3ULT

From: siegfried jackstien
Topic: 21532 Message: 21608

Better too long as too short

Yes it will make no difference in performance

It will show a bit different match on the different bands ... so better make it a bit too long an shorten it till you find a good match on all bands

That is what I did here on my 1wl loop

21609. RE: [ham-antennas] UNUN Question on a G Whip Widebander antenna

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-26 13:48:39 UTC
From: jo barden
Topic: 21606 Message: 21609

Hi Shaun

My thoughts. I have had a look at Gwhip website and unless I have it wrong it is a long wire fed via a UNUN as you say. that being the case the impedance will be quite varied to say the least and that is the purpose of the balun. I assume it is basically a 4:1 or 9:1 voltage balun. I would cut a minimum of 4 radials for the lowest band and fit them. I Have been reading "The short vertical antenna and ground radial" by Jerry Sevick and he goes on to say that radial cut to 0.2 wavelengths long and a the more the better (my comment).

if you want to find out the ratio of UNUN just connect a none inductive resistor of 200 ohms across the antenna and counterpoise terminals and on low power it will show as 1:1 SWR if it is a 4:1 or 1:1 when a 450 ohm is connected if a 9:1 ratio.

There may be some improvement in using as a dipole then you would not need extra counterpoises. Sorry talking round in circles. I would ask what are your requirements? if you use it as a dipole it will make no difference as to what terminals are for what.

That's not to say others might have different expieriences with this specific antenna. So my question.

From what I understand after texting the owner the transformer has neutral terminals.Ie. Either the radiator or the counterpoise can be connected either way on the terminals. Here is what I want to know. This being the case how does the UNUN know which wire is the radiator, or is it looking at both wires as radiators. This been the case then my end-fed would be an osd and the UNUN should be a BALUM.Any help or understanding would Nice. I hope everyone is having a Merry Christmas

Thanking you for any help

Shaun M3ULT

Shaun, I hope you had a good Christmas and a HaPPY, DX FILLED NEW YEAR to you.

I am not familiar with that particular antenna. However from your description, I believe you are correct.
It should work as a semi-vertical or flattop. The 20 meter counterpoise is non resonanmt when close
coupled to ground, becoming a capacitor to ground.
If the far end is grounded to a ground spike, then it is a non resonant OCF but not much.
I suspect the transformer is a voltage balun so either terminal can be attached to ant or counterpoise.

21611. AW: [ham-antennas] my first antenna

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-26 14:34:26 UTC
From: siegfried jackstien
Topic: 21528 Message: 21611

30-35 feet is ok but sure 50 or 100 feet is better
...
On the lower bands every feet counts ...
You can maybe hang it a bit sloped (so use tall and not so tall trees)
Add a pole to the house (put your 2 band vertical for vhf/uhf on it)
That would give you another 10-15 feet over the house to get close to 50 feet

If you have only 3 high points why not build a delta loop ...
So only one point at the house needed ... and 2 tall trees that are in the backyard ... if one is a bit smaller ... who cares?!?

A low antenna is better as no antenna ...

And old timers said if you not make it high ... make it long

So with your 1wl loop you are on the right way

If you have too much sag (cause a longer run) use aluminium fence wire instead of insulated copper

You should add a pull-eye on the trees with a counter-weight if possible

The trees will move in the wind and you sure not want that your wire breaks

On my loop I made a safety thing on one edge:
One rope goes over a tree limp and down to earth in an unused storage room
The rope is secured to a table in the room (do NOT laugh pls) ...
Now if there is a heavy storm the table moves to the door and stays there
Antenna now has a lot of sag and can move free in the wind without too much stress on the wire
When storm is away I just push the table back on its place :-)

Steve, has a very good point, a lot of clubs help out in the communities and those who don't should. Get to know your officials in local government and help with projects in communications and plan support with other groups such as Salvation Army ECOM. Look for Amateurs who are not on the air, get with them and help set up stations. You might find one that is a good ECOM operator and will to stay on the air at their station to maintain communication, but unable to go into the field. Supporting these individuals can become a great asset to a club, begin impaired should never be consider an handicap to anyone, every one in a chain makes it stronger. WA5GHR

Tune for lower end of band should bring you in center when it is up
You could check how mch it is changing with the height ... put it down ...
make correction for lower band edge ... put up again

21616. AW: [ham-antennas] Coax for Loop antennas V factor etc

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-26 14:52:03 UTC
From: siegfried jackstien
Topic: 21494 Message: 21616

Dough
Vf has nothing to do if the shield has more or less strands (or is a copper tube) ...
So it is not a question if population is dense ort not)or if shield is dense or not)
Vf is dependant from dielectric material used ... and if it is a massive or foam insulation (more air= higher vf)
Massive coax inner insulation mostly shows vf of 0.66
And foam or cell insulation shows higher numbers)around 0.8-0.85
So you have to KNOW the EXACT VF ... or you have to measure it ...
Or cut your stub to resonance with ananalyzer

That's a great idea...

Would really like to see the results of a model comparison of, oh say, a few, one wavelength loops, made of various materials, from copper, aluminum up to some 'RELATIVELY' higher resistance metals...

Also, it would need to be done with normal diameter conductors vs really fine stuff...

I'm banking that the conductor size, would quickly exagerate the resistivity difference.

For this one, I may just break down and jump into EZNEC!

Actually, considering the challenges of having antennas in some areas, this has been one of the most intriguing questions I've seen on this group.

If those radials are on the ground, length will not matter. If they are elevated radials, then yes, adjusting length will help, but that is really putting a bandage on a problem, not the correct solution.

Dwayne,

I have a 52' crank-up...

My CushCraft tri-bander is optimally tuned at the fully extended position...

This summer we had a lot of high winds, so, I lowered the tower about 1/3'd...

WOW...my SWR curve moved down a good 100khz to 200khz depending on the band!!

So, I'm not surprised at what you are seeing.

Topic: 21528 Message: 21622

Sigi brought up a good point that is often left out when talking about any wire antenna. You should add a pull-eye on the trees with a counter-weight if possible
The trees will move in the wind and you sure not want that your wire breaks.

All new antenna builders should remember this, when supporting the antenna with trees the weather can cause problems, wind and ice will break a wire unless you have a strain relief. A pulley with a simple weight, a brick or two will work, or a table but I have never tried a table.

To: ham-antennas@yahoogroups.com
Subject: AW: [ham-antennas] my first antenna

30-35 feet is ok but sure 50 or 100 feet is better
...
On the lower bands every feet counts ...
You can maybe hang it a bit sloped (so use tall and not so tall trees)
Add a pole to the house (put your 2 band vertical for vhf/uhf on it)
That would give you another 10-15 feet over the house to get close to 50 feet

If you have only 3 high points why not build a delta loop ...
So only one point at the house needed ... and 2 tall trees that are in the backyard ... if one is a bit smaller ... who cares?!?

A low antenna is better as no antenna ...

And old timers said if you not make it high ... make it long

So with your 1wl loop you are on the right way

If you have too much sag (cause a longer run) use aluminium fence wire instead of insulated copper

You should add a pull-eye on the trees with a counter-weight if possible

The trees will move in the wind and you sure not want that your wire breaks

On my loop I made a safety thing on one edge:
One rope goes over a tree limp and down to earth in an unused storage room
The rope is secured to a table in the room (do NOT laugh pls) ...
Now if there is a heavy storm the table moves to the door and stays there
Antenna now has a lot of sag and can move free in the wind without too much

stress on the wire
When storm is away I just push the table back on its place :-)

I don't know where Amphenol makes theirs, but, I found half a dozen of them, still in the wrappers, for real cheap, at a recent hamfest...

If you can find, the real, genuine, in the wrapper, Amphenol as surplus, go for it....

And YES, YES, YES, there can be just a great big, huge, whopping difference in the quality of the PL259...

Definitely, go with good ones and save yourself some aggravation!

I had a similar experience with my Yaesu rotor many years ago. They always claim it was lightning damage. The design of the control box is pretty old technology. It is overly complex considering todays resources.

The required function is pretty simple. The motor assembly runs at about 15 volts in high speed. I found mine does fine (with only an A3S Cushcraft) at the 12.6V that runs my station. It draws less than one amp. A DTDT-center off switch will provide motion. There is a 500 ohm (approx) pot that senses the current position. If you put an ohmeter on the center of the pot and the other lead on the right wire it comes pretty close to indicating degrees. I ran that way for a year or so while I fiddled with a microprocessor controller.

I only work on the project occaisionally and it is currently at the point where I turn a knob to indicate the desired heading and the rotor seeks that heading. The LCD also indicates a little more info that I used in debugging. It works too good! It is installed in a cardboard box and still on a prototype board. I never dreamed it would work this well this many years. I decided that I wanted to add some more features (control from computer, control from logging program, control from Ham Radio Deluxe, etc.) so I have not taken it further. I have a lot of projects like this that I will never really get finished considering I am nearing my 72 birthday!

It does not look too difficult to simply duplicate the origional functions in the Yeasu box. The fancy motor driven indicator looks like a standalone servo driven indicator. Also, keep the power supply. The rest is easy to replicate with a microprocessor.

There are commercially available replacement control boxes that look good to me. Check out the Ham vendors. I considered pursuing it as a product but my AADD kicked in and I never got around to it! I am really happy that the world named my Adult Attention Deficit Disorder! Perhaps some one will pick up this bit of information and put an affordable product together.

There are not too many of us old "fix it" guys around any more. It is even more rare to find one that works for a vendor. A few years back I needed an extinct part for my still in use power supply that came with my Yaesu FT-301D transciever. A casual conversation on the air with a ham in South America led to a part number for a kit from Yaesu (less than $10!) that replaced the part. Ordering the part from Yaesu (Vertex) was no problem. I got a spare. I cannot volunteer to help you with your unit because I am too far behind. I still have not fulfilled an earlier promise on this forum regarding a 6 meter beam computer model! I have had a great life & it keeps getting better... 73 W8CCW SK

If all the work of up & down is overwhelming, Consider putting it in position and giving it a try. If the SWR works out greater than where you want to use it, put an antenna tuner at the radio end. All you are going to loose is in feedline losses. The antenna will work fine. The first time up will be the hardest, you will learn a lot!

Greetings,
You may call Mauser Electronics in Texas as they google with Amphonel,and see what they know. Radio shacks just melt when soldering the inner connection.
Amphonel used to make the best along with other American companies.
Germany is also known for quality merchandise but, company names are unknown to me.
Good luck,
George

The answer is: This list seems to not be populated with "big mouth know it alls", as many are.
Seems we users don't always know where our materials are made, unless they are marked conspicuously.

Can you call the various manufacturers and ask? We'd like to hear what you learned, no doubt.

I am not sure about the PL-259 but I have two Stihl chain saws and the one made by Stuttgart Germany is much better quality than the one made in America. I made the mistake of buying the American one first.

So do they make PL-259's over there, we don't make much over here anymore?

21636. Re: [ham-antennas] are there any PL-259 connectors still made in the USA?

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-26 21:49:21 UTC
From: Stephen Bennett
Topic: 21526 Message: 21636

Thanks for the link, I forwarded it to the lady who makes up my Coax, she was the one who gave me the info. I even found a forum which said they weren't made in the USA anymore... very interesting how false info gets spread around.
That's why I asked the group, I wanted to be sure. I thought I had checked the company website, but maybe I failed to do that, but at least I asked the group.

thanks very much!

the reason I asked? one of the connectors on a coax I bought failed, I had just hooked it up and decided to move the radio. and noticed there was a sharp edge. When I took a closer look when I got it off I saw a tiny 1/16th of an inch where the metal had separated just at the edge of the cup, it wasn't much, but it shouldn't have happened and indicated to me, I thought, that the metal was of inferior grade. So I sent it back and asked , "are these made in the USA? and the answer was "none are made in the USA" so I asked the group.

Steve

again, thanks for your help

It seems only reasonable ... why should your vendor or their vendor tell
you
something that may lead you to another source. After all, it's not your
best
interest they are looking out for.

This thread really makes me laugh ... how long ago did we look upon the
Japanese stuff with the same disdain. Now they are considered "high
quality" !!

Remember the flap about product marked ..."Made in USA"... , right except
it was Usa, Japan !!

21639. Re: are there any PL-259 connectors still made in the USA?

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-26 22:54:22 UTC
From: AB2ZY
Topic: 21526 Message: 21639

The country of origin is less important than the specifications and tolerances of the manufactured product and verifying same.

Manufacturers in China run the gamut from GMP & ISO9001 certified facilties to counterfeiters and outright criminal adulterators.

If you are going to source parts from China and quality is important to you, you have to commit resources to regularly auditing your offshore suppliers and ensuring that the product is what you and your customers expect.

In a number of industries, it is almost impossible to source components or chemicals that are entirely China free. You have to know what you are buying or run the risk of assuming a potentially fatal liability.

As an example, most people know about the Chinese dog food that was sold through Wal-Mart that poisoned a number of pets. One of the ingredients was adulterated with melamaine, a plastic that "fools" the standard tests for protein content. Melamine is apparently cheaper than sourcing an ingredient that meets minimal quality standards. American and European infant food manufacturers usually avoid Chinese ingredients because the risks involved, but they are also able to charge a premium for their products to cover the additional cost. Not widely reported in the US was the number of Chinese children who were poisoned in exatly the same fashion by Chinese manufactured infant formula.

Hi Ron,

Jeffrey D Clagg came through with a company in Rochester NY, Andros Manufacturing

http://www.androsmfg.com/index.php?option=com_content&view=article&id=77&Ite

Which does proudly proclaim "Still made in the USA"

http://www.androsmfg.com/images/stories/AndrosMAF.pdf

Looking at the PDF file, a picture of the Space station, and reading it says that their N connectors are being used on the Space Station

So Jeff came through, stayed on topic !

Thanks again to Jeff

The answer is: This list seems to not be populated with "big mouth know it alls", as many are.
Seems we users don't always know where our materials are made, unless they are marked conspicuously.

Can you call the various manufacturers and ask? We'd like to hear what you learned, no doubt.

Al,

Granted specifications matter but so does country of origin. It is this type of thinking that is causing manufacturing plants to close in the US and why jobs are being outsourced to lower cost regions.

I would pay a premium to things made in the US, just so the specs are what they need to be. This " it does not matter where it is made" mindset is giving US the Walmart mindset at the expense of American jobs. Do I mind where it is made. Heck yes.

My 2 cents.

73,
Robert

The country of origin is less important than the specifications and tolerances of the manufactured product and verifying same.

Manufacturers in China run the gamut from GMP & ISO9001 certified facilties to counterfeiters and outright criminal adulterators.

If you are going to source parts from China and quality is important to you, you have to commit resources to regularly auditing your offshore suppliers and ensuring that the product is what you and your customers expect.

In a number of industries, it is almost impossible to source components or chemicals that are entirely China free. You have to know what you are buying or run the risk of assuming a potentially fatal liability.

As an example, most people know about the Chinese dog food that was sold through Wal-Mart that poisoned a number of pets. One of the ingredients was adulterated with melamaine, a plastic that "fools" the standard tests for protein content. Melamine is apparently cheaper than sourcing an ingredient that meets minimal quality standards. American and European infant food manufacturers usually avoid Chinese ingredients because the risks involved, but they are also able to charge a premium for their products to cover the additional cost. Not widely reported in the US was the number of Chinese children who were poisoned in exatly the same fashion by Chinese manufactured infant formula.

21646. Re: [ham-antennas] Re: are there any PL-259 connectors still made in the USA?

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-27 07:10:22 UTC
From: Todd F. Carney
Topic: 21645 Message: 21646

I've been reading this thread off-and-on since it began. I've resisted adding anything because my ideas are not nearly as useful as I usually think they are. I have, though, thought about the following.
*
*
1. This Yahoo group is available Worldwide to anyone with access to the Internet, perhaps even in China. It would be interesting to know how many subscribers are not United States citizens. I suppose a rough idea could be had from counting non-K or non-W call signs.
*
*
2. I've also wondered how many American hams proudly display QSL cards from around the World; some winning DX awards and acalades for reaching out and touching the World with their signals on all modes. Flip though any QST or CQ and you'll find pages of listings each month.
*
*
3. I found the following quote from the ARRL site very interesting

With worldwide wireless communications, hams are also ambassadors for their country. Radio provides the opportunity for communications with hams in nearly every other foreign country. There are over 600,000 radio amateurs in the United States and over 2,000,000 worldwide.

I had no idea that American amateurs make us less than a third of the total number around the World!
*
*
*4. Given all this, isn't just a little unbecoming for amateurs in the United States to make public in a World-wide forum their concerns about "foreign" manufacturing and "cheap" labor abroad? *
*
*
***Beats me! But I'm going to think more about this and, in the meantime, to forebear to display my understandable patriotism and national pride with fellow hams around the globe.
*
*
*
Best to all,
*
*
Todd

Have you forgotten the standard Walmart add BEFORE Mr. Sam Walmart died?
Almost every ad said *"MADE IN THE USA!"* He died and in less than a month
everything started saying "Made in China"
He supported America and became the richest man in the USA, all the kids
want is
FATTER PAYCHECKS, Screw the USA!

I will not buy from Walmart.

My $0.02 worth on this.

You need to be very careful on what is written on packaging, many manufacturers have changed from "made in ***" to "country of origin ***".
The latter means the country the item was packed in, so if the manufacture if a product is in China
and its packaged by a manufacturer in the country you live in, they can put "country of origin < your
country>" and you buy it thinking you are buying a home grown product.
Not all products from China are crap, some are of equal and better quality, there are however companies
that fraudulently produce goods that are marked in compliance with national standards and often carry
brand and trade markings of reputable companies.
BTW its not a problem that just the USA now suffers from, its global.

The mantra that is promulgated this side of the pond is there are some things that it is not cost effective to make in our economy and we should only make/manufacture "value added" products and leave the lower input cost (wages) to the new economies. This is all well and good if you are in well paid employment and can afford to buy into this modern disposable economy.

I am unemployed (back condition) so finances dictate that I go for lowest cost that will do the job also I am by nature a "tight" person in that I want to maintain and repair if all possible. This fits in with the green agenda and also there is a prejudiced opinion in the general public that the "Murdoch" press promotes that if you are on benefits you are a lazy scrounger and you should not afford anything other than "value" products. Sorry off on moan.

I would say that whilst buying the locally made 259's may be difficult Tentec make some pretty good equipment. You also have MFJ, LDG and SGC so you have more local content than we do.

Subject: Re: [ham-antennas] Re: are there any PL-259 connectors still made in the USA?

*I've been reading this thread off-and-on since it began. I've resisted

adding anything because my ideas are not nearly as useful as I usually

think they are. I have, though, thought about the following.*

*

*

*1. This Yahoo group is available Worldwide to anyone with access to the

Internet, perhaps even in China. It would be interesting to know how many

subscribers are not United States citizens. I suppose a rough idea could be

had from counting non-K or non-W call signs.*

*

*

2. I've also wondered how many American hams proudly display QSL cards from around the World; some winning DX awards and acalades for reaching out and touching the World with their signals on all modes. Flip though any QST or CQ and you'll find pages of listings each month.

*

*

3. I found the following quote from the ARRL site very interesting

With worldwide wireless communications, hams are also ambassadors for their country. Radio provides the opportunity for communications with hams in nearly every other foreign country. There are over 600,000 radio amateurs in the United States and over 2,000,000 worldwide.

I had no idea that American amateurs make us less than a third of the total number around the World!

*

*

*4. Given all this, isn't just a little unbecoming for amateurs in the United States to make public in a World-wide forum their concerns about "foreign" manufacturing and "cheap" labor abroad? *

*

*

***Beats me! But I'm going to think more about this and, in the meantime, to forebear to display my understandable patriotism and national pride with fellow hams around the globe.

*

*

*

Best to all,

*

*

When I go to a Ham Fest I look for old PL-259 that have turned black, They are the silver plated connectors and them disassemble and clean them. Hamfest prices are almost free.

There's quality stuff made in the usa. There's cheap crap made here too.

The same 2 statements can be applied to anywhere else. Blanket assertions anything from some particular place is good or bad, categorically, are evidence of contempt-prior-to-investigation.

I run open wire feeders and fuhgeddaboudit.

From: kb7gl
Topic: 21645 Message: 21653

MODs, can this topic be put to rest? I think we all 'get it'.

73, Vic KB7GL

Dave, I sent your story to "Yaesu" (as a complaint) and I received this reply, this is the best
that I could get from them. This is their reply:

<<
Ron,

I would like to give you more information, but I am not allowed to speak on customers repair
details. The unit was not under warranty and there is much more involved than what was told to you
and the website. The customer was given the best service possible and if the unit was under warranty, we would have taken care of it had it fallen under our warranty terms. If the unit was
within the 1 year warranty and it was not repaired, then that would mean that the unit had damages
that were not covered by our warranty. I cannot go into details, but I will hope that you can
understand what I am saying by that and understand that we do our best to try and help the customers
at all times when possible.

Thank you for your support of Yaesu radio.

Regards,
Scott Dolliver
Customer Service Manager
Standard Horizon
Yaesu Amateur Radio

I buy from max-gain. Silver plated, teflon core. $2.35 with RG8X reducer. Never had a problem. They solder nicely and do not suffer core melt-down. Price and quality matter. I do not care where he gets them from.

Jeff, it is about 3:1 at the feed, but since I have a balanced open line feed, I lose very little in the line. I do match it at the rig with my tuner. Dave, WA6TXU.

From: goldtr8@charter.net
Topic: 21605 Message: 21657

FYI my 2 WL loop is made from galvanized guy wire. Not sure the gauge number though.

~73
Don
KD8NNU

On Mon, Dec 26, 2011 at 4:24 AM, kj6ddf wrote:

I asked the question about the galvanized wire 20/22 ga, and as it happens, I'm also disabled, but I didn't want to start a war! Talking over ideas with a experience amateur who does a lot of experimenting building loop antennas, he mentioned that he had build an antenna once using galvanized steel fence wire, and I wondered if anyone else ever heard of it. But it wasn't a cost cutting measure, I think it was an experiment.
And even if one is very short with their budget due to disability, I think the suggestion about getting help from a local amateur club is an excellent one!
I've had chronic pain for 22 years, was born with a back condition (insert my own ridiculously long probably very boring story) and the best thing I've learned with God's help is to look at what I have, not at what I don't have...

And as it just so happens, I did recently visit a local Amateur club, I was concerned if I'd be able to attend, because I tend to prefer my recliner and two heating pads, but I went and was very glad I went. And as it also just happens, they talked about putting up antennas for others, I didn't ask, it was my visit, but after a few came over to say Hi, and after followed up with emails, and I asked if it were possible to give me some help putting up the loop antenna I ordered. I ordered a "store bought" ready made antenna, because with my disability, a.) wire antennas are inexpensive b.) I'd probably make some stupid mistake c.) I'd end up in a lot of pain trying to build it myself, and that's more costly in doctor visits (copays etc.) than getting it done by the techs at a company.
But I hadn't thought of getting help from the club. I was going to stumble around in the yard, try to shoot a line over branches and probably realize after I threw my neck and back out how over my head I was (Often I'm able to easily "think" a project through, without realizing I can't do what I used to be able to!)
But after going to the club, and I got a mental picture of younger healthier club members who have experience putting up antennas, and most of all, (don't forget the coffee and donuts/ bucket of chicken/ Bar-B-que) the close friendships that will be built in the process!

That's what so wonderful about amateur radio and clubs!

So I would imagine that if someone didn't have the funds necessary, a club would be willing to help.
Sitting there at the meeting, I didn't say anything, I was there to observe. I hear them say over and over, "How can we help out in the community?" "how can we help others?"

they must have said it a dozen times? they set up a committee to look into it! I am sure other clubs also want to help others!

Forgive me for being long winded, just wanted to say, I didn't know how much help was out there, and I often sit in my chair afraid to go anywhere because of the pain I might get into, (I'm in enough pain already sitting on the heating pads) but when I did go the local amateur club, I was so happy. And I hope others who are disabled also find the same help I did. For those not able to get out, I believe local clubs would respond favorably to a request for help, by phone call or email.

anyway,just my 2 cents worth

Steve

OK here is a simple question and we'll see who gets the answer correct first.

This morning my 80 Meter dipole was resonate at 3.755. Now it is resonate at 3.650.

My 40 meter dipole was resonate at 7.150. Now it is resonate at 7.040.

What changed the points of resonance on those two dipoles?

Ok let's see who gets it right the first time around. Of course the person who posts the correct answer will be the winner. No one can copy that answer :)

Sounds like you had a good snow fall and the wet snow has changed the
antenna height above ground lowering the height and frequency.

Did the resonance change, or the SWR?

(It's a trick question, a few days ago there was a very long discussion on another list about the differences between low SWR, matching, tuning, resonance, etc. It even got into whether we were discussing the "resonance" of the antenna, or the antenna, feedline, tuner, etc.)

Hi,
Did the Eldridge from the Philadelphia Experiment re-appear at the same
time, (or close to the same time), that the SWR changed?

All I can think of is adding wire to each end, or maybe an inductor at each end. Or if you used the old parallel telephone drop wire split apart for the antenna elements, you pulled another foot or two apart to add antenna length. All I can think of.

Hi,
Did the Eldridge from the Philadelphia Experiment re-appear at the same time, (or close to the same time), that the SWR changed?

OH Rick!
You are way off!!!

It snows more in N AZ (Navajo County, for temperature and 10 to 20 miles east of Holbrook, AZ for snow and cold!! More than 28" so far this year) than it has in Michigan (9") this year and been FAR colder last year -45 (Minus 45) while Michigan at the same time was about 25 at night at the same time!! Last year was about the same differance for total years snow fall!
I moved from that part in March this year but was here in Lansing, MI, at the time it happened and talked to friends still there last year and this year.

You want cold and snow live in N AZ, nice weather live in Michigan!!

21668. Re: [ham-antennas] Re: are there any PL-259 connectors still made in the USA?

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-28 09:35:38 UTC
From: Stephen Bennett
Topic: 21645 Message: 21668

At Andros we make and sell PL259 connectors and reducers for RG59 coax. We also make the 2 piece N connector that solders on like a PL259. We also make many different styles of F connectors.
We do not sell to the general public. We sell only to distributors and other manufacturers. We do have a $500 minimum order.
If you …or your vendor..would like to place an order or just call to talk about them please call me at 585-663-5700.

Russell Steenhoff
Andros Manufacturing Corp.
30 Hojack Park, Rochester, NY 14612
Phone: 585-663-5700 Fax: 585-663-1212
email: russell@...
web: www.androsmfg.com

There is only one "on Topic" message that has been on this tread, all the others are on an entirely different topic, "something to do with trade wars and the quality of things made in every place etc.

I just had a connector fail that wasn't made in the US, so I wanted to find out if anyone knew of any company that still made them in the US.

Only one person, Jeff, replied to the question asked and stayed on subject.

I followed up with the link Jeff gave me, and this is what they told me, I'm going to forward it to the lady who makes up my coax, she makes a lot of coax, so she should be in a position to buy $500.00 worth of connectors.

I've noticed many threads both in this group and in other amateur groups that get off topic and get folks acting in a manner that others begin to complain.

It's so sad.

Anyway, this was a very simple question, it's been anwsered and I followed it up with what I found out. So I'm through with the topic.

Anwyay fellow amateurs, lets have a good time and get along ok?

When I go to a Ham Fest I look for old PL-259 that have turned black, They are the silver plated connectors and them disassemble and clean them. Hamfest prices are almost free.

The mantra that is promulgated this side of the pond is there are some things that it is not cost effective to make in our economy and we should only make/manufacture "value added" products and leave the lower input cost (wages) to the new economies. This is all well and good if you are in well paid employment and can afford to buy into this modern disposable economy.

I am unemployed (back condition) so finances dictate that I go for lowest cost that will do the job also I am by nature a "tight" person in that I want to maintain and repair if all possible. This fits in with the green agenda and also there is a prejudiced opinion in the general public that the "Murdoch" press promotes that if you are on benefits you are a lazy scrounger and you should not afford anything other than "value" products. Sorry off on moan.

I would say that whilst buying the locally made 259's may be difficult Tentec make some pretty good equipment. You also have MFJ, LDG and SGC so you have more local content than we do.

Subject: Re: [ham-antennas] Re: are there any PL-259 connectors still made in the USA?

I've been reading this thread off-and-on since it began. I've resisted adding anything because my ideas are not nearly as useful as I usually think they are. I have, though, thought about the following.

*

*

1. This Yahoo group is available Worldwide to anyone with access to the Internet, perhaps even in China. It would be interesting to know how many subscribers are not United States citizens. I suppose a rough idea could be had from counting non-K or non-W call signs.

*

*

2. I've also wondered how many American hams proudly display QSL cards from around the World; some winning DX awards and acalades for reaching out and touching the World with their signals on all modes. Flip though any QST or CQ and you'll find pages of listings each month.

*

*

3. I found the following quote from the ARRL site very interesting
With worldwide wireless communications, hams are also ambassadors for their country. Radio provides the opportunity for communications with hams in nearly every other foreign country. There are over 600,000 radio amateurs in the United States and over 2,000,000 worldwide.
I had no idea that American amateurs make us less than a third of the total number around the World!

*

*

*4. Given all this, isn't just a little unbecoming for amateurs in the United States to make public in a World-wide forum their concerns about "foreign" manufacturing and "cheap" labor abroad? *

*

*

***Beats me! But I'm going to think more about this and, in the meantime,

to forebear to display my understandable patriotism and national pride with

fellow hams around the globe.

*

*

*

Best to all,

*

*

Wet snow changed the SWR, happens all the time in this part of the country. I shook the dipoles and got most of that snow off and during the evening it got a lot colder and froze. Now it is windy so I think most of the snow is off the wires as things are just about back to normal.

Topic: 21673 Message: 21673

Hi All Likely to be replacing my current Windom with a Doublet. Considering the following. G5rv a proven performer is 51ft on a side with the odd 30ft of LL. A 30m extended zep is about 62 Ft on a side with the odd LL. Can I have some opinions on how this will play as a mulitband antenna vs the traditional G5rv. 30m, 40 and 20 are my main bands of interest for this antenna. Let me know what yall think.

I think this is a common misunderstanding. SWR is the result of the match between the antenna
impedance and the feedline impedance, this isn't going to change greatly, not nearly as much as the
tuning will change with outside influence. An antenna on a different frequency is not an antenna at
the frequency you are operating on. If you are operating on 20 meters with a 40 meter dipole the
load will reflect the energy instead of radiate it, the 40 meter dipole will still be a 73 Ohm match
to the 75 Ohm coax. (at 40 meters)
I keep my 40 meter dipole very tight with a 1/2 concrete block (rope over a pulley at one end) to
minimize the physical movement of the antenna wire to keep the tuning as I set it. Tight between
two trees without the ability to change means wire breakage. (it doesn't snow in central Florida)

I posted to one of the group members offline, and got no answer
I put together a 2 element 10 meter antenna, I will feed it direct, This was an old CB 3 element beam
I cut the boom to about 6'-6" to start just a dipole with a director/reflector.
I used PVC insulator on the elements.
I am new to antenna modeling software meaning just learning.
My question is should I use a RF choke 8"x 8 turns or a 1:1 Balun.
What would be the most effective.
Using Rg 213/u coax- 50'
left over from CB days.
I do not have the funds for an analyzer yet, I figure
if I can get a good swr, I will just go for it
I am putting it 35 feet high roof mounted tripod apex is 25'
10 foot mast.

Well you asked what we "think", not for factual data ;-) IMO the G5RV is a bizarre antenna designed for the purpose of an easy coax match on multiple bands. It does that because the "feedline" is part of the antenna and the matching system.

A clean dipole (of any length), is a cleaner design and an efficient antenna when properly fed (open wire or ladder line to a good tuner for multiband use). Of course, under specific conditions, any one antenna may perform better than another antenna.

BTW, you use the term "doublet". I'm not sure what exactly a "doublet" is since the term is not defined in any of my ARRL Handbooks or Antenna Books and Bill Orr doesn't even use the term. Decades ago, I used to think it was a folded dipole but I have nothing to support that old assumption. I'm guessing that a "doublet" is just a fancy (and confusing) term for a plain old dipole.

The "poor man's choke" (coil) will minimally effect the match between the antenna and the line.
The driven element of a Yagi is a dipole, is it's impedance is about 73 Ohms (at the designed
frequency) and the "proximity" of the reflector lowers the it's impedance to near about 50 Ohms
The SWR will be low if the element is tuned to your operating frequency.
Frequently the length of the elements are adjustable to finalize tuning.
The line between the driven element and the choke coil should slightly spaced from the metal parts.

Incorrect. Yes, it will be reflected back and forth until it is radiated, just like an antenna on it's fundamental frequency. Unless you have high loss feedline. A 40m dipole (e.g. 67') is "two half waves in phase" on 20m, a very efficient radiator with a slight amount (1.8db) of broadside gain. Of course, it is a high impedance feed and should be fed with open wire or a matching system to minimize losses.

> the 40 meter dipole will still be a 73 Ohm match
> to the 75 Ohm coax. (at 40 meters)

The radiation resistance of a half wave dipole is only 73 ohms at certain heights above ground. It can vary from below 50 ohms to almost 100 ohms depending upon height above ground until it gets up high enough that the ground no longer effects it, at which point is is around 73 ohms.

A "doublet" is an OLD name for a center fed dipole.
Dipoles can be fed anywhere, "doublets" are only fed in the center.
"Dipole" means both poles of the "wave" (a cycle) are on the conductor at the same time.

"it will be reflected back and forth until it is radiated, just like an antenna on it's fundamental frequency"

I respectfully disagree. If it were all radiated eventually, there would be no need to resonate
an antenna at our operating frequency. Your 40 meter dipole would work just as well at 6 meters as
an antenna designed to operate on 6 meters, (all Yagi's would cover 160 to 6 meters) this is not so.
The source of RF (transmitter via any tuning equipment in use) is a lot closer to the impedance of
the transmission line than a 40 meter dipole fed with 20 meter energy, so it will only reflect some
of the energy. It will dissipate much of it.
If you feed a high power tube amplifier that is properly operating at 20 meters into a 20 meter,
antenna into a 40 meter dipole and it will arc at it's tuning capacitor and generate a great deal of
heat. If you feed a transistor amplifier (such as your transceiver's output amplifier) with the
"fold back" disabled you will *melt* the output transistors.
The transmitter will absorb much more reflected power (from the wrong antenna) than a 20 meters
signal feeding a 40 meter dipole. (the wrong antenna)
Some energy will leak out and be radiated, but not much, not enough for you to think everything
is fine.

When the term doublet was common, coax was not yet in use by HAMs, many doublets were fed with
"zip cord" at the time.
Coax became available to hams, first, as surplus from WWII.
A "doublet" is a center fed dipole.

It must be a VERY old term since my books go back 50 years and rarely use it and never define it ;-)

I guess an OCF is a dipole, but an end fed ("Zepp") doesn't qualify IMO. Likewise calling a center fed antenna a "Zepp" is an aberration!

I do cringe every time I hear an OCF used with ladder line called a "Windom", at least without a qualifier. '8GZ must be rolling in his grave :-(A true Windom is fed with a single wire.

A center fed 80m half wave fed with open wire is an excellent antenna for all bands, 80 through 6, assuming you have a proper antenna tuner or a transmitter that will match it.

Don't confuse antenna efficiency with directivity. They are not the same. An 80m center fed dipole fed with open wire on 20m will be more "efficient" than a 4 element Yagi. Yes, a Yagi will direct more energy in a specific direction, but will radiate less total power than a dipole. It just directs the power, but at a cost.

Of course a Yagi will not work across all bands because the parasitic elements need resonance of their own.

As to your statement that a 40m dipole on 20m will operate terribly, again I suggest you read the ARRL Handbook or the ARRL Antenna Book and look up "Two half waves in phase" antenna. It's a great antenna and the basis of beams like the Lazy-H, and the 8JK (designed by John Kraus, the author of "Antennas" probably the best professional classic antenna book).

As for as capacitors arcing over in a final amplifier, that is not an indication of lack of efficiency, but rather the transmitter not being designed to handle high impedance loads. The classic Johnson Viking II transmitter will load virtually any antenna without arcing or overload.

Oh, one other point: many antennas (perhaps most) operate perfectly fine without being "resonant". Most AM broadcast antennas are not "resonant" but rather are designed to operate above their point of resonance in order to better direct their power.

Do not confuse an apparent low SWR with resonance. They are not the same.

Ken,

There may be losses in the yagi design, but you must agree that a yagi is a much more well rounded antenna design over a dipole as not only can you point your radiated signal in the area you want, you can also decrease your beamwidth and increase your forward gain just by adding more directors. Front to back ratio and the ability to reject or attenuate signals off the backside of the beam is also another redeeming factor of a yagi over a dipole.

The ease of installation of a dipole over a yagi is to be noted, but a yagi are most ham's choice of antennas.

A center fed 80m half wave fed with open wire is an excellent antenna for all bands, 80 through 6, assuming you have a proper antenna tuner or a transmitter that will match it.

Don't confuse antenna efficiency with directivity. They are not the same. An 80m center fed dipole fed with open wire on 20m will be more "efficient" than a 4 element Yagi. Yes, a Yagi will direct more energy in a specific direction, but will radiate less total power than a dipole. It just directs the power, but at a cost.

Of course a Yagi will not work across all bands because the parasitic elements need resonance of their own.

As to your statement that a 40m dipole on 20m will operate terribly, again I suggest you read the ARRL Handbook or the ARRL Antenna Book and look up "Two half waves in phase" antenna. It's a great antenna and the basis of beams like the Lazy-H, and the 8JK (designed by John Kraus, the author of "Antennas" probably the best professional classic antenna book).

As for as capacitors arcing over in a final amplifier, that is not an indication of lack of efficiency, but rather the transmitter not being designed to handle high impedance loads. The classic Johnson Viking II transmitter will load virtually any antenna without arcing or overload.

Oh, one other point: many antennas (perhaps most) operate perfectly fine without being "resonant". Most AM broadcast antennas are not "resonant" but rather are designed to operate above their point of resonance in order to better direct their power.

Do not confuse an apparent low SWR with resonance. They are not the same.

Robert,

of course the Yagi is an excellent antenna and ideal for many uses. I was just approaching the issue from the "efficiency" standpoint and the claim that a full wave center fed dipole was high loss and inefficient.

With a Yagi, you give up a bit of efficiency (especially on a multiband trapped Yagi) to gain directivity and rotate-ability. A long dipole is more "efficient" (in regard to losses) but probably will direct the radiated energy into unwanted directions. So a Yagi may be more useful even if it is not quite as efficient.

Sorry to cause any confusion.

Ken WA8JXM

> There may be losses in the yagi design, but you must agree that a yagi is a much more well rounded antenna design over a dipole as not only can you point your radiated signal in the area you want, you can also decrease your beamwidth and increase your forward gain just by adding more directors. Front to back ratio and the ability to reject or attenuate signals off the backside of the beam is also another redeeming factor of a yagi over a dipole.

Ok Now that we have gone off on the tangent of what a doublet is. To me a doublet as stated by a few other is a Dipole fed at the center. Where just a dipole can be fed at any point.

So I will ask again. I don't mind totally biased opinoins. Ive got lots of those of my own. But any body try this? Or should I just put it up in the atenna range and see what works best here?

Thanks I love this list

When the term doublet was common, coax was not yet in use by HAMs, many doublets were fed with
"zip cord" at the time.
Coax became available to hams, first, as surplus from WWII.
A "doublet" is a center fed dipole.

John I have not tried a 30m 5/8wl I did do it 20m, work fine, but as the frequency went up towards 10m it became very directional off the ends. Not quite the answer you were looking for but just to let you know what happened to me.

Subject: [ham-antennas] G5RV vs 30m .64wave extened double zep.

Hi All Likely to be replacing my current Windom with a Doublet. Considering the following. G5rv a proven performer is 51ft on a side with the odd 30ft of LL. A 30m extended zep is about 62 Ft on a side with the odd LL. Can I have some opinions on how this will play as a mulitband antenna vs the traditional G5rv. 30m, 40 and 20 are my main bands of interest for this antenna. Let me know what yall think.

> It must be a VERY old term since my books go back 50 years and rarely use it and never define it ;-)

The first time I heard the term "doublet" was in about 1956, more than 50 years ago and it was
explained to me that it was an old term then.

> I guess an OCF is a dipole, but an end fed ("Zepp") doesn't qualify IMO. Likewise calling a center
> fed antenna a "Zepp" is an aberration!

A "Zepp" is a dipole fed with a stub. (of one kind or another) If it's* 1/2 wl then it's a dipole. If you center feed it, it isn't a "Zepp" it's dipole or a doublet.

> I do cringe every time I hear an OCF used with ladder line called a "Windom", at least without a
> qualifier. '8GZ must be rolling in his grave :-(A true Windom is fed with a single wire.

* the radiating part

21698. Homebrew Hustler multi-band mobile adapter question

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-28 21:34:27 UTC
From: wb2hmg
Topic: 21698 Message: 21698

Years ago I made a multi-band adapter for my Hustler mobile mast and resonators. I gave it away several years ago and now find that I need one.

The plans came from one of the ham mags that were out at the time - 73, QST or Ham Radio. The difference between that one and the currently available Hustler VP-1 is that homebrew one could accommodate 5 resonators, where the VP-1 allows a maximum of three resonators.

So, my question is, can anyone point me in the right direction to find the article or another alternative?

Thanks,

Frank

Yes that's the name we give it Poor mans balun,
(I did that on my Cushcraft Tribander,
which I sold and still regret it, had to relocate)
I was just wondering if I should used a premade 1:1 balun instead of rolling my own
maybe I should have just tried it instead of asking questions

I will just try both ways.

Actually, it has to be wet, sticky snow that sticks to the antenna wire.
Just
having snow on the ground will not cause that severe a change.

21708. Re: G5RV vs 30m .64wave extened double zep.

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-29 02:23:21 UTC
From: kd8dvy@ymail.com
Topic: 21673 Message: 21708

I have tried an OCF and a Doublet and both of them worked very well on all bands. I used both on QRPSSB and made several good contacts. However I have a Doublet up now and it is about 65' above ground. With a quick look at the SWR graph, the points that are resonant are between ham bands like the G5RV. As for the OCF the SWR is more in line with ham bands.

The only thing I can say about the two antennas I do not like is that an OCF should be 30-35' above ground. And the doublet is that you have to 99% of your ladder line to the radio. They both take a balun 4:1; 6:1; or 9:1. (Your choice). However a 4:1 is readily available or easily homebrewed.

As for tuning there is not a lot to worry about. If you have a ATU that stores memories all you have to do is lightly tune, store and for get about it. With the manual tuner you would have to write down your tune points so that you will have a reference point to start your re-tune.

Also you may want to ask for someone to help you model the antennas so that you can an idea as to the way the antenna may act.

John I have not tried a 30m 5/8wl I did do it 20m, work fine, but as the frequency went up towards 10m it became very directional off the ends. Not quite the answer you were looking for but just to let you know what happened to me.

Since the feedline radiates, I think it offers a low angle vertical signal good for DX.

Subject: Re: [ham-antennas] Re: Can You Answer This Question?

A center fed 80m half wave fed with open wire is an excellent antenna for all bands, 80 through 6, assuming you have a proper antenna tuner or a transmitter that will match it.

Don't confuse antenna efficiency with directivity. They are not the same. An 80m center fed dipole fed with open wire on 20m will be more "efficient" than a 4 element Yagi. Yes, a Yagi will direct more energy in a specific direction, but will radiate less total power than a dipole. It just directs the power, but at a cost.

Of course a Yagi will not work across all bands because the parasitic elements need resonance of their own.

As to your statement that a 40m dipole on 20m will operate terribly, again I suggest you read the ARRL Handbook or the ARRL Antenna Book and look up "Two half waves in phase" antenna. It's a great antenna and the basis of beams like the Lazy-H, and the 8JK (designed by John Kraus, the author of "Antennas" probably the best professional classic antenna book).

As for as capacitors arcing over in a final amplifier, that is not an indication of lack of efficiency, but rather the transmitter not being designed to handle high impedance loads. The classic Johnson Viking II transmitter will load virtually any antenna without arcing or overload.

Oh, one other point: many antennas (perhaps most) operate perfectly fine without being "resonant". Most AM broadcast antennas are not "resonant" but rather are designed to operate above their point of resonance in order to better direct their power.

Do not confuse an apparent low SWR with resonance. They are not the same.

Wet snow changed the SWR, happens all the time in this part of the
country. I shook the dipoles and got most of that snow off and during the
evening it got a lot colder and froze. Now it is windy so I think most of
the snow is off the wires as things are just about back to normal.

> guessing that a "doublet" is just a fancy (and confusing) term for a plain old dipole.

A "doublet" is an OLD name for a center fed dipole.
Dipoles can be fed anywhere, "doublets" are only fed in the center.
"Dipole" means both poles of the "wave" (a cycle) are on the conductor at the same time.

EEEEEeks! The drawing failed. My version of the doublet was supposed to show a regular center fed half wave dipole, only two parallel lines form each 1/4 wave side. This makes it broad-band. Is my thinking correct?

A "doublet" is an OLD name for a center fed dipole.
Dipoles can be fed anywhere, "doublets" are only fed in the center.
"Dipole" means both poles of the "wave" (a cycle) are on the conductor at the same time.

Amen! They used to be called the Tune and Load controls in the transmitter.
Now they chopped them out and sell them separately.

Wet snow changed the SWR, happens all the time in this part of the
country. I shook the dipoles and got most of that snow off and during the
evening it got a lot colder and froze. Now it is windy so I think most of
the snow is off the wires as things are just about back to normal.

21717. Re: [ham-antennas] Re: "dumming down" "code info"

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-29 12:52:49 UTC
From: doug pfaff
Topic: 21717 Message: 21717

hi Gloria and James

It took me 15 years to beat the code issue because i could not consistently put the initial time in to get over the learning curve needed

Since the WRC of 2000 removed it being mandatory requirement internationally.

watch the 2012 WRC conference as 5 mhz band is up for discussion

This left the code issue for each countries organization to adopt as they saw fit(no code or code) some countries were dead set against dropping code so thats why its not a clear cut issue.

Our regulator Industry Canda has modified things since the WRC of 2000 were code requirement was given a major overhaul internationally.

These WRC conferences put everything on the table for open discussion internationally every 4 years

Check with your FCC (usa regulator) to see where they went with the code issue, check out the reciprocal agreement area to see how you operated in other territories

hear are some code learning tips

1) using tapes did not work for me as you were hearing sounds but you got to memorize them over time then the real exam blew you away

2) use your computer using Super Morse Program

3) Setting up the timing factor is critical so the all the sounds come out right so they sound like real world code
4) Set the learning charture speed at 18wpm so each letter is a sound
5) Find out the tone you hear it best at, in my case had to lower it from the default setting.
6) Find your best time of day to learn, mine was before going to work from 6:30 am to 7:00 am where your brain is relaxed.
7) Use the learn function so you learn each letter well initally, use the words to really find out how they sound put to common use
8) Then use the random characters groups to become proficient when you get about 90% right plain code will be super easy.

Punctuation and numbers become easy as they sound totally different

Only use a 30 minute period after that your not learning anything.

I made the mistake of learning it at15 wpm and it took a lot of work to break all the habits.set IT at 18 and hear the difference.

By learning the receive first you know what you have to mimick on the send using a code oscillator.

Here is the benefit if you learn it(code) you will be able to go to most countiries using the reciprocal agreements. Just ask the FCC staff where to find the info on there web site each countries list will be different.

One of the hams here was rusty and he talked to usa novice ham to bring his profiency back up to 12 wpm.

Canada has since dropped it to 5 wpm from the original 12 wpm.if people bas the basic exam with over 85 % mark they automatically get the code endorsement just an exaple of how variable the issue is

Send me your email address direct and i'll pull the discussion off the forum.

Subject: [ham-antennas] Re: "dumming down"

Hi Gloria,

You are not the only one to have a "mental block" about morse code. I am now 67, and first tried learning the code in high school, and then again, off and on, over the next 40 years. There was a point in which the whole thing turned into "noise" and I couldn't tell a dit from a dot. Even with the advent of the "computer age", none of the software would able me to pass the "noise" barrier.... and I bought my first computer in 1978!

I was told to "just keep at it", "keep on pluggin'", and "you're just not working hard enough", etc, etc, ... Finally, I realized that it wasn't "me", but just that the normal methods of learning the code didn't work. So, I started to look around, read a couple of books, tried different things, and may have found a method which works... for me, at least. Apparently, everyone is not "wired" to learn code the same way.

During the Vietnam War era the US Military taught high speed code reception to code breakers using a "sound alike" method... according to a comment I found on a web page. I've found a little information on the web and am using it to give this a tryout... so far the results are encouraging. My goal is to be able to communicate with CW at 15wpm... not very lofty, but a major life accomplishment for me.

Now... to stay on topic.... my opinions as far as "dumming down" is concerned... everyone has different talents to bring to this very large table called "ham radio". Morse code is just another operating mode and we should have done away with its high speed requirement 20 years ago. If we want to restrict ham radio, lets have the test contain binary and hexadecimal math problems! That's important stuff these days. How about having test takers write a two page paper on "string theory"?

Just kidding! Ham radio is a large house with hundreds of rooms and doors. There's something interesting going on in every one of those rooms. I've found "my" rooms and am having a great time!

> With a quick look at the SWR graph, the points that are resonant are between ham bands like the G5RV. As for the OCF the SWR is more in line with ham bands.

SWR does NOT indicate resonance. Resonance often may not provide a low SWR (especially on a center fed dipole with open wire).

A low SWR is only important with coax feed.

If you are unconvinced, let me put it this way: a 130' center fed dipole fed with open wire. Will it have a high SWR on 80m? yes. Will it be resonant? YES. 40m? High SWR but resonant as "a two half waves in phase collinear". 20m....15....10.... yes, yes.

There are techniques to adjust the feedline as a matching transformer, but that usually only works on one band.

But the bottom line is: SWR does not necessarily indicated resonance and resonance does not necessarily provide a 1:1 SWR. SWR is a measure of the impedance match between the feedline and the antenna, not a measure of resonance, especially when using ladder line or open wire.

Now there is nothing wrong with adjusting your coax fed antenna for lowest SWR, that's good, but only an issue with coax feed.

Your drawing came through fine here.

There are several ways to make a dipole more broad banded:

-- make a larger conductor by using parallel wires tied together at the end. When you do this with 3 or 4 conductors, it's called a "caged dipole" I believe.

-- use two (or more) conductors not tied together at the end but of slightly different length. Basically a fan dipole but for a single band instead of multi band.

-- use tubing for the antenna. That's only practical at UHF frequencies.

I'm not sure that it's really worth it except on UHF. Yes, it will lower the SWR a bit but most rigs can handle the SWR from a single wire dipole anyway. On UHF frequencies where the additional coax losses could be important and it's easy to use tubing, it makes sense.

> 4) Set the learning charture speed at 18wpm so each letter is a sound

I believe that different things work for different people.

However, I highly recommend AGAINST the idea of learning with fast letters and wide spacing. Too many people are learning that way and never learn proper spacing and send really, really horrible CW. They can't send CW worth a darn!

What worked for me: no machines, no tapes (I tried that and failed). I just mentally repeated to myself "di dah A di dah A" many times until I started thinking "A" automatically when I heard "di dah". Then another random letter from the alphabet, maybe "di dah di R", repeated many, many times. Again, that's what worked for me. Other approaches work for other people.

But please, let's stay away from this characters at 18 wpm with spacing to bring it down to 5 wpm! Please don't put that on the air! Or 25 wpm characters with spacing for 12 or 15 wpm. Please, no!

Maybe they have done us a disservice by discontinuing the novice bands. It used to be that one knew where to find stations using slow CW: the 50 kHz in the novice bands. Perhaps the ARRL and other organizations need to jointly recommend frequencies in each band for slow speed operation.

Could we perhaps agree that "doublet" is an archaic term that no one agrees on what it means and therefore should be dropped in favor of less confusing terms? :-)

Someone the other day said that it dated back to when hams used lamp cord for feedline. Since lamp cord feedline is obsolete, let's put doublet into the same basket and bury it!

My understanding is that a dipole when fed with ladderline and used
multiband then its name is a doublet

A dipole is mostly a resonant thing and very often fed via a balun and coax
(1:1 when cen6terfed, 1:4 or 1:6 when off-center fed)
Multiband with fanned dipoles or traps

A doublet is very often NOT resonant on any of the hambands but made a
resonant system with the ladderline and the tuner

And lamp cord is still available :-)

But now we use ladderline instead of the lamp cord

So the name doublet should not be thrown in a basket ... but used correctly

Wow! First time I ever heard that! I have seen the Handbook call it a "Zepp" which I believe is another gross corruption :(

>

It's popular with some autotuners to use 100' centerfed antenna as a multiband antenna. Since it's not "resonant" would that mean it's not a "dipole"? To me, "di-pole" is "di" (two) pole (sections).

>
> A doublet is very often NOT resonant on any of the hambands but made a
> resonant system with the ladderline and the tuner

I'm not touching that one! Already had a recent discussion on another group of whether "resonant" applies to the just the antenna, or the whole system including the tank circuit or tuner inside the transmitter. With the later definition, all antennas are "resonant" :roll eyes: My old Viking II transmitter can load a 3' steel fishing pole on 80m. I refuse to consider that "resonant".

>
> And lamp cord is still available :-)

But I hope no one is using it for feedline!!!
>

> So the name doublet should not be thrown in a basket ... but used correctly

And who will decide what is "correctly" since it is an ill defined term (none of my ARRL pubs define it and Bill Orr doesn't even use the term). In the dictionary, I think it's a piece of clothing ;-)

Ken

The Canadian exams were based on knowing sounds instead of Di Dah which you could easily mimics at 5 wpm test

The whole idea is learn as "sounds" it much easier so you don't get trapped in the Di Dah trap later as word get into the higher speeds ,back prior to 2000 we had to know code at 12 wpm much like the American 15 wpm or 20 wpm class at that time.

I have seen it first hand in my kitchen back in the 1980's from military trained hams from northern Canada and they go by the sounds(HE WAS COPYING CODE AT 25 OR 30 WPM WITH NO PENCIL AND TOLD ME THE GIST OF THE CONVERSATION).he was a dew line operator from 1960 and 1970 in Northern Canada and he told me the secret is knowing the sounds made and not having to think.

I really believe this as that's how I passed my code at 12 wpm level here in Canada prior to 2000 when the WRC downgrade it to 5 wpm internationally or to the no code requirement.

Try supermorse program properly set up and set it at 15 then 18 work character speed and see the difference its Huge.

Our Canadian examiners would not pass us unless the spacing was right so we got no breaks if we could not send decent code.

I've had exposure to this hobby since the early 1970 when you had only two things to get a Canadian license if both element were not passed within 1 year you started over, a very difficult technical exam that I passed after studying at post secondary tech school and code proficiency at 15 wpm send and receive.

Did not pass code till the 1990 when I got off the road and was able to dedicate the time to it.

Best wishes for 2012

I believe that different things work for different people.

However, I highly recommend AGAINST the idea of learning with fast letters and wide spacing. Too many people are learning that way and never learn proper spacing and send really, really horrible CW. They can't send CW worth a darn!

What worked for me: no machines, no tapes (I tried that and failed). I just mentally repeated to myself "di dah A di dah A" many times until I started thinking "A" automatically when I heard "di dah". Then another random letter from the alphabet, maybe "di dah di R", repeated many, many times. Again, that's what worked for me. Other approaches work for other people.

But please, let's stay away from this characters at 18 wpm with spacing to bring it down to 5 wpm! Please don't put that on the air! Or 25 wpm characters with spacing for 12 or 15 wpm. Please, no!

Maybe they have done us a disservice by discontinuing the novice bands. It used to be that one knew where to find stations using slow CW: the 50 kHz in the novice bands. Perhaps the ARRL and other organizations need to jointly recommend frequencies in each band for slow speed operation.

Good observations.

I originally learned the code from a record, but got only to the 5 wpm for my novice test. To get above that, I used the W!AW code broadcasts. I just worked at it two or three sessions a week, not worrying about progress, and eventually discovered I could copy sporadically at 30, solid at 25. Below 20 wpm, they send the characters at around 18 wpm and put spacing between them. This forces listeners to hear sounds, not count dots and dashes, even at low speeds. Above 18 wpm, the code is correctly spaced, so the listener gets to hear perfectly formed code.

Try to listen for words. CQ, QRZ, the, es, and other common combinations are easy. Then you just have to fill in.

It is certainly true that some people just don't have an aptitude for it. My advice would be not to worry about progress, but just listen and copy for as long as you can. When it all starts to run together, as it did for me at times, just stop and do something else.

GL with the code.

Doug,

I don't understand what you mean by "the di dah trap". I'm not talking about memorizing dot and dash, but rather the sounds and having my mind automatically relate that to a letter. Hear a certain sound, think a certain letter (and eventually print that letter).

FWIW, I got my (5wpm) novice in July 1963, my 13 wpm General four months later and my 20 wpm Extra in 1967 when they implemented Incentive Licensing. All but the novice was in front of FCC examiners and we had to have one full minute of perfect copy, no answering questions about what was sent, you had to have 13 or 20 consecutive words perfect copy. Likewise we had to send by hand.

I developed an automatic reflex with my fingers twitching the pencil when I heard certain sounds. Sometimes I had to look down at the paper to see what had been sent. It wasn't until 25 years later that I started copying in my head and broke the 30 wpm barrier. I literally used to _print_ 29 wpm.

Ken

Our Canadian code requirements were 3 minutes of copy and could review and fill in missing info but you were allowed only 3 errors.

Punctuation and Q codes and number were automatic 2 errors each.THEY SENT 3 5 LETTER/NUMBER CODE GROUPS AT THE END THAT YOU COULD NOT MISS on as it was automatic fail the test.

Sending was by hand key only

My military friend didn't even write it down even at 25 or 30 wpm.

Your first statement of sound only is the secret.

A lot of the people who know how to teach code are quickly becoming silent keys sadly

Best wishes for 2012

I used a buddy to learn to get to the 5 wpm for my novice. Then the
best way to gain speed is simple.

USE IT!

Simply getting on the air and talk to people with it will increase your
speen in no time.

Plus

IT IS FUN!

From: dean
Topic: 21717 Message: 21733

I have a Great Nephew studying for his test. I told him if he could learn code then he can get on 15, 40 and 80 meters and it won't wake his parents if he's doing it late at night. I think code is great and if I could learn it I'd be on the air with it only.

The last time I tried code I'd say the ditty ditty dah dah's out loud till the wife told me to shut up. When the tape went into a fast flurry of code I was totally lost. So I don't know code.

I might give your way a try there Ken. It would be cool when the wife drives I can send and receive code from the car while she listens to her talk radio.

73, WY6L

I believe that different things work for different people.

However, I highly recommend AGAINST the idea of learning with fast letters and wide spacing. Too many people are learning that way and never learn proper spacing and send really, really horrible CW. They can't send CW worth a darn!

What worked for me: no machines, no tapes (I tried that and failed). I just mentally repeated to myself "di dah A di dah A" many times until I started thinking "A" automatically when I heard "di dah". Then another random letter from the alphabet, maybe "di dah di R", repeated many, many times. Again, that's what worked for me. Other approaches work for other people.

But please, let's stay away from this characters at 18 wpm with spacing to bring it down to 5 wpm! Please don't put that on the air! Or 25 wpm characters with spacing for 12 or 15 wpm. Please, no!

Maybe they have done us a disservice by discontinuing the novice bands. It used to be that one knew where to find stations using slow CW: the 50 kHz in the novice bands. Perhaps the ARRL and other organizations need to jointly recommend frequencies in each band for slow speed operation.

73,
Ken WA8JXM

By not working I mean I can't just push the darn button to get it to tune. However when I first got it I went thru each band every 20 KC's and tuned the radio. It works well manually if I put it in cw and hit the key, but I just wanted a button push. If I get the YF-450 from LDG then it'll just be a button push. Shoot me for being lazy.

I have remote based my FT-950 but the three antennas don't work on all frequencies. If I let others use my radio, they would have the proper license so no problem there, and want to work 20 meters it only works with the beam not the dipole. Sort of frustrating. But I digress.

I have an external tuner and it works fine with my FT-950. Can't understand why your external tuner works with your FT-857D and not with your FT-950?

From: kb7gl
Topic: 21673 Message: 21736

I think the term originated with the long-wire end-fed antennas reeled out of the old Zeplins, and later, airplanes. I recall seeing those same HF antennas in the C-119 "Flying Boxcar". They left several weights hanging on fences just off some airports, when the line was neglected to be reeled-in prior to landing!

I've also enjoyed this discussion string -- I'm going to experiment with the ZS6BKW variant vs. a 130 ft dipole with ladder line direct to my balanced tuner, to see which performs best. If the ZS6BKW performs as well, it eliminates more than just some minor tweaking of the tuner on most bands. (The ZS6BKW is similar to a G5RV, only shorter and with SWR "dips" at the majority of amateur bands.)

Well like I told my nephew and his parents that I have a lot of modern gear and I'm happy to share with him. My thought is get them interested and then keep helping them out. If not a problem loan them one of the older VHF,UHF radios till they can buy their own.

I'm willing to put a bit of my money in cheap radios to help out new hams. We can't get new people as we do not try enough. I don't care what the other guy does but I do try to tell everyone about ham radio. Like my mobile contact on 20 M just south of Salem, OR. Get with a Boy Scout leader to teach radio to the scouts so they can get their amateur radio merit badge.

Another thing is have the club set up a radio booth at your local fair. Let people know that when the cell tower goes down ham radios will still be here on a lot of frequencies. Maybe young people would like to get involved with AREA/RACES.

My Niece told me nobody wants to sit next to my nephew as all he talks about in school is ham radio. Maybe he can get one person involved in the hobby.

sorry for the rant

You have it backwards...

All center-fed dipole are doublets...

Not all doublets are dipoles...

A dipole, by definition, is EXACTLY 1/2 wavelength long.

The reasons why the young do not want to get involved in ham radio is more than the list of an earlier poster. One of the reasons in addition to other technology taking the place of ham radio is the present generation is an entitlement generation. They do not want to work for anything, they expect it to be given to them.

Young kids look up to gangster rappers, sport figures and movie stars. When was the last time you heard a 16 year old say that they want to be the next Albert Eienstein. Never. The priorities of the up and coming generation in western society is not on math and science.

This is the reason why many countries have to import their intellectual workforce.

We have taken down most of the roadblocks in ham radio testing and young people still do not embrace it. The only swelling of the ham ranks are the people on the sidelines who stayed out of the hobby as they did not want to put in the work to learn the code or study the extensive theory in the past. Look at the demographic of the new hams.

Now what do we have, a bunch of bands that are filled up by contesters pushed by the ARRL to make the bands seem full so that the frequencies seem utilized so that the commercial or military do not take the spectrum. We have some new operators who have terrible operating practices and bring in their operating practices from CB radio.

Yes, we have received some good new hams since the lowering of the license standards.

The thing that scares me is that if you were known to be a ham radio operator 20-30 years ago, you were given a bit of respect even in professional circles, as it was known that if you were a ham, you were known to be technical.

Recently I was at my local ham club meeting when a licensed ham asked what a repeater was.

The hobby is changing. In my opinion less challenging to become a ham and therefore some much less technical hams. Yes, it is a hobby, but as you lower the standards for anything, you get less qualified people into that human endevour.

Submitted as my personal opinion and through quantative analysis.

Before flaming on my comments. Do your own analysis and draw your own conclusions.

73,
Robert

Well like I told my nephew and his parents that I have a lot of modern gear

and I'm happy to share with him. My thought is get them interested and then keep helping them out. If not a problem loan them one of the older VHF,UHF radios till they can buy their own.

I'm willing to put a bit of my money in cheap radios to help out new hams. We can't get new people as we do not try enough. I don't care what the other guy does but I do try to tell everyone about ham radio. Like my mobile contact on 20 M just south of Salem, OR. Get with a Boy Scout leader to teach radio to the scouts so they can get their amateur radio merit badge.

Another thing is have the club set up a radio booth at your local fair. Let people know that when the cell tower goes down ham radios will still be here on a lot of frequencies. Maybe young people would like to get involved with AREA/RACES.

My Niece told me nobody wants to sit next to my nephew as all he talks about in school is ham radio. Maybe he can get one person involved in the hobby.

sorry for the rant

73, WY6L

Ham radio is a dieing entity! Look at the average age of ham radio operators. We can't get new people because of the following reasons

1) No one wants to help them get started

2) Cost of good gear

3) cell phones

4) video games

5) No one will help them (o wait i said that)

Just one persons view

I am a new HAM since 2008 and upgraded to General in 2010. Proud of it and because of HAM, I have been involved with Emergency Preparedness. During most of these events, I have been getting people interested by demonstrating it's importance. Been lucky so far. Have seem a tremendous growth in Hawaii of upcoming HAM operators in the Hospitals. Never had the privilege to learn code and that is one of the things I would like to do. In Hawaii, you need at least two jobs just to keep up with the basics for rent. But I will still be a HAM. Had a Stroke earlier this month and just slowed down a bit but will not stop. Our club now has at least 4 young people with at least Techniclal. I believe that is a good start.

Ernie,
You are certainly entitled to your opinion, factual or otherwise.
Fact is, the number of hams in the US has been increasing. I don't think that's a sign of a dying entity. The age of operators is, in my opinion, irrelevant. We've always been a bunch of old fuds no matter what ages we are.
I don't think "nobody wants to help them get started". I think there are not enough Elmers out here. Remember, though, we're ALL Elmers at least potentially. If you wish to preserve your beloved hobby, get out there and do it. You don't like "appliance operators"? It's uo to YOU to teach them so they'll know what they're doing.
The cost of "good gear" is another matter. We all know you can put a perfectly viable station on the air for next to nothing. If you're focused on keeping up with the Joneses, it'll cost you some money.
We have to set a good example for prospective and new ops. We need to emphasize that you don't need a KW to ragchew 300 miles on 75 meters. A well-operated FT-101 is indistinguishable from an FT-2000 on the receiving end and costs a lot less.
As for cell phones and video gear, I have both and they don't stop me from operating. I elmered a "gamer" a few years ago and he's now immersed in hamming. He operates more than I do! CW too.
I think a lot of old-timers need to change their attitudes about the FNG's to make ham radio more welcoming to them.
That's MY opinion! 73

As Dave said earlier, what does this have to do with antennas? QRZ's Discussions, Opinions & Editorials works well for this. Food fights do not belong here...

OK. Here ya go:

Is ham radio growing?

Look at the numbers!

At the end of 2010 there were 696,041 Amateur Radio licensees in the USA.

Here are the past totals for the USA:

2010 □ 696,041

2009 - 682,497

2008 - 663,564

2007 - 655,842

2006 - 656,068

2005 - 662,600

Also important...

Higher percentages of Amateur Radio licensees are going far beyond the initial Technician Class license and earning General or even Amateur Extra Class licenses.

The numbers were steadily declining until '07 when the code requirement was dropped. These figures are from the ARRL.

What do the numbers prove. You drop or lower the requirement for anything, the numbers will increase, as someone has less work to get the same operating privledges. Just wait till there is no test at all. The numbers will go through the roof, but then it will then it will just be another CB radio with more frequencies. I will sell my equipment at that time and spend more time in one of my other hobbies. The supporters of the lower test requirements have already impacted the hobby, if the no test supporters get their way, the hobby will have one less ham.

Sent from Samsung Conquer™ 4G

urei <ureii@...> wrote:

Hi group: I been experimenting with my 135' off dipole down in the cw subband ...at 3535kc the antenna presents a feedpoint z of 33-j155 according to arrl-nec. The transmission line program that comes with the antenna book tells me that at the other end of 44 feet of 600ohm open wire line that z is transformed to still-low-r but the reactance is transformed to * Plus* 600-odd ohms. Does this sound right??

I can send the necessary file if need be...

From: kb7gl
Topic: 21717 Message: 21750

Well, it gets tedious reading through the long strings. I frequently DO read about this topic, and have done some recent "elmering" myself. However, I prefer to do it on the appropriate forums. Where I see the harm is that these strings inevitably evolve into 'peeing matches'; it seems more important to be "right" than rely on facts. And, they seem to go on forever, with no one convincing the other.

Having said all that, it's hard to deny that the hobby is, indeed, growing. Aside from the supporting facts stated earler, one can look at the N4MC Ham Locator link; punch-in zip 98033 and you'll see the huge number of new hams, virtually all kids, that have been brought into the hobby over the past several years, through the efforts of a local grade school teacher, and the Lake Washington Hams club, which is primarily for kids (K7LWH). Granted, this is only a local effort, but I believe it is happening all over the USA.

Ok -- you sucked me in...there's MY opinion. :-)

> Zepp = endfed dipole fed via quarterwave ladderline transformer

I agree 100%. Well, wait a minute, end fed with open wire, I agree. But I wouldn't call it a "dipole" since it doesn't have TWO (di-pole) sections. And I don't know that it needs a quarter wave transformer. Originally transmitters used link coupling and could match high impedance balanced feedlines.

> Double zepp = similar to doublet

I would call that a open wire fed dipole. Unfortunately (IMO), I found one Handbook also calling that a Zepp (cringe!)

The term "Zepp" came from the open wire, end fed, trailing wire used by Zepplins. They didn't/couldn't use a dipole (center fed) antenna. Anything beyond that, IMO, is a corruption. Might as well call a center fed dipole a Yagi :-(

Sometimes I think half of our problems is that there is no longer a standard of what terms mean so people use them loosely and communications is poor :-(

No test? In your dreams! Just because the ITU and FCC drop an archaic requirement doesn't signify a trend. Outrageous claim.
Have you listened to 80 meter phone lately? THERE'S a
real CB-type mess! AMers and SSBers arguing about who's entilted to what portions of the band, filthy language nightly, jammers, CW in the phone segments, phone in the CW segments. And the majority of these lids are old-timers, code-qualified hams.
If you limit ham licensing to strictly engineers and technicians that's when you'll lose your precious hobby. There aren't nearly enough to support ham radio.
Who is advocating no-test licensing? This is the first I've heard of it.

I produced numbers to back my claims. Your turn. Mike

--- In ham-antennas@yahoogroups.com, "Robert Costa, KB6QXM" <kb6qxm@...> wrote:
>
> What do the numbers prove. You drop or lower the requirement for anything, the numbers will increase, as someone has less work to get the same operating privledges. Just wait till there is no test at all. The numbers will go through the roof, but then it will then it will just be another CB radio with more frequencies. I will sell my equipment at that time and spend more time in one of my other hobbies. The supporters of the lower test requirements have already impacted the hobby, if the no test supporters get their way, the hobby will have one less ham.

OK, I'm still learning how to edit text on my new smartphone...the fist couple lines of that message [i.e. everything before "Hi group" was mistakenly not edited.

And it was SUPPOSED to end "I can send the NEC file..."

Sorry abt that.
73, Brian KA9EGW

Topic: 21717 Message: 21757

Ernie, I will agree that #3 and #4 are definite issues, along with there is no longer the "magic" of communicating with people far away like there used to be.

As for your #1, well I learned it all by myself as a teenager. I had no outside help. I had my ticket for a dozen years before the term "Elmer" was used. I think many ham clubs today do more mentoring than they did 50-60 years ago.

Your number two I vigorously disagree with. Ham gear is cheap today compared to 45-50 years ago.

1968: Drake Twins and power supply: $1200, about half the price of a new car in or equivalent to 3600 gallons of gas.
Now: Many good HF transceivers for $900-1200, which will buy you less than 10% of a new car or 300 gallons of gas.

Back then, the top of the line ham gear (Collins S-Line) cost about 6 months average wages.

The one advantage 50 years ago was that old TVs could be torn apart and the parts used for ham gear. And there was WWII surplus gear available although most of it wasn't all that good by the 1960's standards.

This hobby seems to be riddled with negativity.

Anyone in this argument trying to defend the positive numbers is wasting his time. There will always be someone who will have a negative reply.
Just like, no matter what ANY President of the USA does, past, present or future, there will be those who just cannot give credit where credit is due.
Their minds are made up. Do not confuse them with facts. Best to just drop the subject and move on. They will also tell you that an antenna does not radiate even though we all know that it does.

Best Regards
Dan Schaaf

If the outer ends are connected, it's a folded dipole, if not it's a sort
of fan dipole, and the 'cage effect' of the doubled elements should
broardband it...somewhat...

I'm guessing you meant this:

=====||=====

not this:
|=====||=====|

Well, doubling the license period reduces the turnover. Yes, there are more licensees now than ever, but the activity on the bands is way, way down from what it used to be.

And the age of the operator does matter since as these older folks become silent keys, the numbers will drop. Back when I started as a teen, it was very common to work other teens on the air. How many teen age kids have you worked lately?

Ken

The term hasn't died in 75 or a hundred years, whom are you to close the door on part of our
history? It is still accurate and used, it's just that everyone hasn't met the term yet, like about
a hundred other less common terms. Such as: "I prefer double ended amplifiers."

> Someone the other day said that it dated back to when hams used lamp cord for feedline. Since lamp
> cord feedline is obsolete, let's put doublet into the same basket and bury it!

Zip cord isn't gone or obsolete, it is a perfect back packing feedline and feedline antenna combination. It weighs less and will fold without having to observe a "bending radius" precaution.

"two wires in parallel" is different than a folded dipole. Physically the wires in a folded dipole are in parallel, but not electrically.

Topic: 21717 Message: 21766

It is not a requirement to be on the air regularly to be a ham. Many hams do experimentation, antenna design and testing instead of being on the air all the time. And many are into QRP SOTA, mountain Climbing, back packing, biking with their small radios. Many hams have a family and a life outside of the hobby, wives, kids, dogs, camping, sports etc etc.
It is only the addicted ones like contesters and DXers like myself who are on the air all of the time.

So, just because the bands seem quiet, doesn't mean that there is no ham activity of some sort.

Well, doubling the license period reduces the turnover. Yes, there are more licensees now than ever, but the activity on the bands is way, way down from what it used to be.

And the age of the operator does matter since as these older folks become silent keys, the numbers will drop. Back when I started as a teen, it was very common to work other teens on the air. How many teen age kids have you worked lately?

Hope I don't start a new fire here .
what is not mentioned is how many of the new hams actually get on the air or advance beyond technition . I took the extra exam when I passed general and failed it . no surprise there as my math skills are not good . never tried again as what it will gain me is not enough to make it worthwhile for me since most of what is gained in in the CW bands and I am not a CW operator .

> What do the numbers prove. You drop or lower the requirement for anything, the numbers will increase, as someone has less work to get the same operating privledges. Just wait till there is no test at all. The numbers will go through the roof, but then it will then it will just be another CB radio with more frequencies. I will sell my equipment at that time and spend more time in one of my other hobbies. The supporters of the lower test requirements have already impacted the hobby, if the no test supporters get their way, the hobby will have one less ham.

Couldn't agree more -- a zip cord antenna/feed line works very well, and rolls-up into a tight little package to keep in my motorcycle saddlebag. The only connections are at the end of the feed line-- nothing to break. If I was backpacking, I might get rid of the insulation weight, but on the MC it's not a big deal.

I believe in America, a doublet has always been simply a "center fed" dipole.
A dipole can be fed in any way and by any means.

But all of that was also true 50 years ago when the bands were more active. I'll give you that yes, there may be active hams that we don't hear on the air, but still, the HF bands are very lightly used today compared to 50 years ago.

The only band that I hear more use on today than 50 years ago is 160. Back then it was overrun with LORAN stations, we had very limited use and few rigs could operate on 160 (mostly Johnson equipment.)

I worked VK3ZL on 160 today and heard XU7ACY. 160 is a listeners band since you spend most time listening for something.
It may be more active now than back then but this season has been a bust due to high SFI keeping the D Layer into absorbtion mode all night

Personally, I do not lament at the lack of use of the bands. It makes it easier to find a clear spot, although this cycle, 12 and 10 have been busy.

One of my favorite bands is 60 meters.
I have WAS on 60 and 61 countries on 60.

Make that two, I help when I can, I had a terrible time finding help.
Good gear is cheep, just not new. Everything else is quite valid.

Not everyone would ever want to become a HAM. Showing HAM radio at schools and to scouts* is
imperative. There is a (US) HAM radio program for scouts.

I said the source of my numbers. You just saw only what you wanted to.

Yes, I was thinking of a folded dipole---thanks for reminding me.

If the outer ends are connected, it's a folded dipole, if not it's a sort
of fan dipole, and the 'cage effect' of the doubled elements should
broardband it...somewhat...

I'm guessing you meant this:

=====||=====

not this:
|=====||=====|

The "Zep" is an end fed dipole, it can be fed with anything including "Zip cord." It's not the
materials it's the nature of the feed.
It is a dipole because both "poles" are on the wire at the same time. (One complete sine wave.)

OMG I think I better read the old posts some more. You are right. SWR does not mean the feedline is radiating if it's balanced, right?

I'd still like for somebody to explain to me what's so terrible about an off-topic thread.
My wife belongs to a group with a very specific topic but off topics are accepted and sometimes pretty extensive.
The moon hasn't fallen out of the night sky and the seas haven't dried up. What's so awful?

I could not help but respond to this thread, and there may be some fellow members of my club here. I was a member of this club when it was shrinking and dying, and not really interesting. This club is now thriving like never before, and is interesting. Read the story. Last meeting I attended I could hold and examine radios and antenna parts that were prototype or backup to the first satellites in space.

http://nfarl.org/phoenix/

A very active Yahoo group that lets members put their gear for sale there....courtesy takes follow-up elsewhere...etc. Seen plenty of good solid state gear there for sale at really low prices I could go operate before buying, way better than unknown ebay stuff.

They do scouts.

They reply to help with antenna hanging, or any other issue technical, very technical or not.

They have weekly tech-net open to all on echo-link with background chat session, on Monday nights

They have a weekly 2 meter youth net.

Cram-Jam full day session for licensing.

Almost monthly VE sessions close to home. Made my Extra upgrade with one missed question a breeze, not having to drive more than 5 miles. Took the test on Saturday of Field Day Weekend. They expected poor attendance, the room was packed almost to capacity. Most were General or Extra test takers, across all age groups.

YUP, the hobby is dying, everywhere you do not have a true community club like this one has turned around to be.

Exception, yes, rule no....why not?

Nothing necessarily, but that's not the point. The idea that this group is not good for anything if it's not open to anything ham radio related is what's moronic.

Between eham, qrz, contesting.com, Yahoo and the General class portion of 75m, there are literally thousands of places to hang out and socialize. I, for one, don't mind the occasional diversion as long as it doesn't become the norm and drown out the real purpose of the forum.

This group, IMO, is more welcoming to the novice than tower talk and many of the other antenna related forums. As a result, it tends to be a bit repetitive and less technically sophisticated. THAT'S OK! It's a valuable resource as-is and I'd hate to see the SNR drop to zero.

removing the insulation from zip wire would not reduce the weight much . all that would happen is that you would have a tangled mess to unravel everytime you wanted to use it . the wire strands also tend to want to separate by themselves . I used to have a fan diploe made with the old radio shack wire kits , bout the only useful item they had the last few years until they discontinued it . I kept it neatly coiled up and tied as it only got used on field day , everytime I went to use it and untied the coils to hang it , it took 45 minutes to untangle and separate the 6 wires . replaced them with 14 gauge automotive primary wire and solved that problem .

What is "so terrible" is that It is just plain poor etiquette and bad manners....there are plenty of other more appropriate forums if you want to rant about no code licensing and the like

The stated purpose on the group home web page in RED LETTERS says basically "anything about antennas" That pretty much leaves out politics, religion, building power amplifiers, low noise preamps, organic gardening and the state of the amateur radio community at large.

Sort of like calling the dx station on his frequency repeatedly when he says "up"

In the mean time i will continue to wear out the letters on my keyboard "DELETE" key, I pity however the poor blokes who have to read this forum with a dial up modem

Fred - I wasn't inferring that one should remove the insulation from zip cord -- if backpacking, I would use an antenna made from spooled solid magnet wire or something similar - zip cord would be excess weight. Every ounce counts, when on one's back -- in my saddlebags, not so much.

Sorry but no.

The Zepp goes back to the Zepplins and what they used was open wire feed. Of course people can call a fish a cow if they want to, but that doesn't make it easy to communicate. And as I mentioned earlier, I've even seen the Handbook call a centerfed antenna a Zepp. As long as everybody wants their own definitions to be flexible, nobody will know what they are talking about.

And there is NOT a "complete sine wave" on a half wavelength antenna, you need a full wavelength for a full sine wave.

I always thought that a "real" Zepp -- first used on the Zeppelins and trailed out of their cockpit -- is a half-wave dipole end-fed with a quarter-wave matching section. This is the origin of the J-Pole design. Of course, they were rather long in the Zeppelin days, below 200 Meters.

John,

I have a 102-ft doublet (same length as a full-sized G5RV) fed with 100 feet of 450-ohm ladder line (although the length doesn't matter) connected to a wide-range tuner (MFJ-998). It tunes 80 to 6 meters quite well except for 15, which is OK on the low end of the band, but unusable over 21.1.

It works quite well on 40, 30, and 20. I've worked lots of DX on these bands, as well as local and medium-distance stations.

By shorting the ladder line leads and working against long radials, it also loads on 160.

If you have the room, try it. MFJ sells one for about what the ladder line would cost from most suppliers.

You are correct, a Zepp is a half wavelength long antenna (dipole) fed at one end with an "impedance inverting quarter wavelength long transmission line." Much like a "J" pole antenna,
except in the "J" pole antenna the "impedance inverting quarter wavelength long transmission line"
has a shorted end, and a elevated feed point allowing precise impedance matching.

All,

Thanks to the back and forth of many off topics, I believed it was time to start a new group where open conversation about anything ham radio, good or bad will be allowed. The name of the new group is called Ham Radio Open Conversation. This will be a place for you to openly discuss ANYTHING ham radio and on occasion off topic.

Everyone has an opinion.

This group is open to discuss ANYTHING about ham radio. This group will be open to discuss Ham radio in the past, Ham radio presently and opinions of what ham radio will be in the future based on observations.

I believe in free speech. You can discuss anything ham radio. Code versus No code. New license exams versus old license exams.

Anything. The two above were just two possible subjects.

This is your area to discuss anything ham radio.

ARRL or any ham organization. Good or Bad comments.

This is to debate ANYTHING ham radio related.

If you decide to join this will be your forum. Be heard. I will allow anything short of verbal threats of bodily harm if you disagree on a subject.

Open debate is good, if both parties allow debate. Please be open to debate and not just simple rants.

Please try to base your comments on research and not conjecture.

As this forum is open to all subject relating to ham radio and some off topics, if you are easily offended, this forum may not be for you.

73

I saw the need, so it might take the off topics to a forum that all comments are welcome.

Great point, Gary. It starts sounding like the old 75 meters where a guy tells how he ran a modulated 6v6 one tube transmitter that was a regin receiver. Alright, already.

Moderator input.....Off topic discussions that are HAM radio related work
sometimes in the short term because they usually die a natural death. This group is for antenna related topics but sometimes we moderators let the topics waver off course. Unfortunately, we sometimes have to step in and return normality to the group. Now is the time. Back to antenna related topics please. Take the other topics offline or to another list that allows
off topic discussions.

What is "so terrible" is that It is just plain poor etiquette and bad manners....there are plenty of other more appropriate forums if you want to rant about no code licensing and the like

The stated purpose on the group home web page in RED LETTERS says basically "anything about antennas" That pretty much leaves out politics, religion, building power amplifiers, low noise preamps, organic gardening and the state of the amateur radio community at large.

Sort of like calling the dx station on his frequency repeatedly when he says "up"

In the mean time i will continue to wear out the letters on my keyboard "DELETE" key, I pity however the poor blokes who have to read this forum with a dial up modem

21806. RE: [ham-antennas] Impedance transform

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-30 05:23:01 UTC
From: KA9EGW
Topic: 21749 Message: 21806

It gets even weirder...ARRLNEC tells me the feedpoint Z is 35.5-j185ohms, and TLW tells me my feedline transforms it to 58 PLUS j449, yet it took 4.6uH in series with one side of the line to get it to where my Johnson Matchbox was happy on 80cw. I can see that; 449 ohms is a lot of reactance to try to tune out with that circuit...but the configuration of the available supports dictated ocf...

What gives?

I'll post the .ez file on the antenna if anyone's interested.

73, Brian KA9EGW

Hi all
I've been watching this thread, and I find Ernies comments hit the nail on the head.But at the risk of
hijacking the thread,this problem is much deeper than just morse or the friendly dinosaurs, hamradiosaurus.
We have managed to produce a generation or two of people that have been educated to pass exams, at the
expense of encouraging the ability to question why something happens.
One the will to ask why something happens or even better to find out why it happens, the latter produces
engineers, and hams, goes you lose an important assett.
And as for the morse , guilty, mine varies between 2 to 5 wpm, dysmorcea. sorry.

On Dec 28, 2011, at 8:08 AM, ko1hqrp wrote:

> Hi All Likely to be replacing my current Windom with a Doublet. Considering the following. G5rv a proven performer is 51ft on a side with the odd 30ft of LL. A 30m extended zep is about 62 Ft on a side with the odd LL. Can I have some opinions on how this will play as a mulitband antenna vs the traditional G5rv. 30m, 40 and 20 are my main bands of interest for this antenna. Let me know what yall think.

Well you asked what we "think", not for factual data ;-) IMO the G5RV is a bizarre antenna designed for the purpose of an easy coax match on multiple bands. It does that because the "feedline" is part of the antenna and the matching system.

A clean dipole (of any length), is a cleaner design and an efficient antenna when properly fed (open wire or ladder line to a good tuner for multiband use). Of course, under specific conditions, any one antenna may perform better than another antenna.

BTW, you use the term "doublet". I'm not sure what exactly a "doublet" is since the term is not defined in any of my ARRL Handbooks or Antenna Books and Bill Orr doesn't even use the term. Decades ago, I used to think it was a folded dipole but I have nothing to support that old assumption. I'm guessing that a "doublet" is just a fancy (and confusing) term for a plain old dipole.

Maybe when you follow up with your lady, you could find out if she does
order them if she would be willing to sell to other Amateur's that do their
own coax?
If so how we might get in touch to order?

With a good tuner it should also work in dipole configuration (so not
against ground) ... and for 15m ... try to add (or shorten) a few feet of
the ladderline and it will work also on 15m
Just do the math
30m antenna and 30m ladderline = high voltage at shack end
(just a rough calculation "over the thumb")

Brian

What was the file posting labeled I cant seem to find it in the files section...email me the NEC file direct (nr1dx@...) if you want, I will be happy to take a look at it

Some general comments on your earlier posts. The impedance transformations you asked about on the 44' of 600ohm line are within reason without doing the actual math. IF your really into this stuff try researching smith charts..a very useful graphical tool for looking at the impedance transformation on a transmission line vs the length of the line

In general it is better practice to try and keep the line balanced which means to say; add equal amounts of series inductance on BOTH sides of the line (not just one) when trying to compensate a line to the point your matchbox can handle it. Adding an additional amount of ladder line may accomplish the same thing

Keep in mind the that the antenna and transmission line programs assume a near perfect world, useful for getting an idea of what is going on but not necessarily a dead accurate representation of what is really going on because of irregularities caused by near objects and real world ground. If your feed line is home brewed is it really 600 ohms or is it 550 ohms or 650 ohms . You can plug the different line values into the programs to see the differences this causes. Are there slight varions in line width especially between spacers etc. While all of this is not really critical to actual operation they are useful to understand if you are trying to understand what you are seeing vs what the program predicts. Since it seems you might be home-brewing the feed-line then plug some different feed line impedance into the computer to see if you get an impedance match for your setup that is easier for the matchbox to deal with and so on, for your application a 400 ohm line of 1000 ohm line may give you a better impedance match at the shack end. Just an FYI most commercial 450 ohm ladder line is really 400ohms

If you are really want to see what is going on in the real world, then build (not hard to do at 3.5 mhz) or borrow a good R-X bridge and measure it . You can use this same bridge to measure the actual impedance of your 600 ohm feed line by the way, if your going to be a purist

New group, same restrictions, just worded differently. Here on this group is supposed to be about antennas, It says 4 or more times that the new group is for discussing Anything Ham Radio.New group was started because of restrictions on old one and restrictions were put on the new one before it even got started. Have replaced the worn out delete button so will stay with the antenna group

21818. Screwdriver Antennas, HOW to use for home use, not mobile?

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-30 15:44:32 UTC
From: van wd8aam
Topic: 21818 Message: 21818

I have a couple of High Sierra Screwdriver antennas,
which had been used mobile. Worked very nicely. Been
sitting in a corner not getting used, started wondering
what it would take for home use.

Let's say I mount one on a camera tripod and put it in the
backyard just outside my shack window. How to you provide
a counterpoise, and what is required.

Also, if mounted on a Mast about 20-35' high,
what type of counterpoise would you suggest.

The main answer is what can I do with a MINIMUM of work
and materials, and also what would I need to do a FULL Blown Luxury
system that works like gangbusters!.

Thanks for any responses,
Van

Van

What bands are you contemplating?

Current wisdom suggests two 1/4 wave elevated radials per each band of interest. If ground mounted then 20 or so "short" (.1 to .2 wavelength on lowest band) radials

your 35' mast will make a better antenna than the screw driver on most bands by the way

How can you get 80 and 160 meters with the ATAS 120? I thought it was limited to 6 thru 40 meters. One of our local hams has the Little Tarheel 2. He changed the whip and can get 10 thru 80 meters well.

If you just going to be putting this in your backyard why not just put up a dipole and do away with the counterpoises. I had a cushcraft R7 and it didn't need counterpoises. Of course it was 10 thru 40.

Amen to that!

By the time you construct a ground plane, there isn't anything a screwdriver antenna will do better than an aluminum pole with a tuner.

Sell the screwdriver antennas on eBay and purchase a remote tuner with the proceeds. Or a commercially manufactured vertical antenna.

Just because you can doesn't mean that you should!

The problem with the screw driver is that it has very low impedance on the lower bands and counts on losses in the coil and ground system to effectively raise the apparent feed point impedance . Also in mobile operation the feed line is very short so any losses due to mismatch are minimal. It is at best a compromise antenna for fixed station operation

Like I said before if I had a choice between the screw-driver and 35' mast I would choose figuring out how to match the 35' mast every time. especially on 160/80/40. On the lower bands the screwdriver is not much better than a tree stump IMO. With the 10' extension they talk about it will be useful on 20-6 with a some resonant elevated radials

21824. Sierra Slims

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-30 16:20:06 UTC
From: dean
Topic: 21824 Message: 21824

I'd like to know if there is anyone else out there who uses the High Sierra hamstick called the Sierra Slim. Somewhere in the northern mountain part of Oregon I made a 20 meter contact with Vienna, Austria and he gave me a 57. No tuner and I have low SWR's from 14.150 to 14.350.

I have the antenna mounted on the back hatch of my little VW Golf TDI. My wife isn't to thrilled with me sitting in the car with my Pro Set Plus and talking while she is driving but generally when I first talk she does turn off talk radio.

I've already got an OCF dipole,(80-6) it works well. I'm just trying to get some use out of the screwdrivers propped in the corner.
And these are NOT ATAS 120's, they are High Sierra's. But they also have limitations, but you can work around. Efficiency at 40-80-160 is much less than with the higher bands.

My mistake I misread the post. My leg hurts from twisting it to kick myself in the butt. I think you can put on a capacity hat on the screwdriver.

So how do you like the High Sierra screwdriver and how long have you been using them.

Well Dave, you've given me an idea. (Dangerous)

What if I put the screwdriver up at 40 feet on a mast, added
some matching coils (if needed) and used it to tune the 80-160 bands
to different areas of each band. Using Base feeding/loading with an MFJ-927
mast style antenna matcher/tuner. Would that add any
options/efficiency/value to
the installation?
Van, wd8aam

21830. Re: [ham-antennas] Screwdriver Antennas, HOW to use for home use, not mobile?

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-30 17:07:49 UTC
From: van wd8aam
Topic: 21818 Message: 21830

I used them about 10 years ago for a winter, (in minnesota much salt)
and the following year there was a corrosion problem. I bought
some new parts, but never went mobile again, but for the one year
it was super fun, a lot of excellent reports on signal strength,
good reception signal strength, etc. But transferred my interest
to my home station, and never used them again.

Uhhhh... number of licensed amateurs has actually been going up the last couple of years. Currently, its the highest its been in the last twenty or thirty years.

If anything, I think it will continue to grow just because the world of "amateur radio" is technologically growing. Look at all the new modes, technical software, and the growing trend for radios to look more and more like computers.

Personally, I have gobs of fun the year round, but only actually operate in the winter time... but that's just me. Well, I take that back... the 2m rig gets used a lot during the summer... but that's just staying in touch locally. Nice radio to have on in the background when doing something else.

If ham radio needs anything, its a little more publicity.

Well that would mean that this group could actually go back to discussing antennas and not the no code issue that has been dead for years (Or it should be because the code requirement isn't coming back ladies and gentlemen)

"Efficiency at 40-80-160 is much less than with the higher bands."
That is the case of ANY "loaded" (or shortened) antenna.
Especially any HAM-stick.
Especially any high "Q" loop that is too small in diameter.

The following is one hams experience. I don't want to start any wars or my ant is better than UR ant lines.

About 25 years ago I ran mobile on 40 and 20 mainly and other bands occasionally.
I tried Hustler center fed , Hamsticks, Master mobile bandspanner, Mark Heliwhip on 40
and a bug catcher antenna.
I had the antennas mounted on the ladder at the back of a Chevy 20 Zimmer Van.
Then on a Honda Civic rear hatchback edge mount. Two extremes of vehicles.
I found the results varied between vehicles, but the final results were very similar

Well the bugcatcher was the best all bands. The BandSpanner was second by a hair and the
heliwhip was next on 40 with the hamstick close behind. The hamsticks for 80,40,20,and 10
were better than the Hustler. However the 15 meter Hustler worked very well.

I liked them so well, I still have the 40 meter mark Heliwhip I bought in 1959 and the mast
and 15 meter hustler coil ands the 20 meter Hamstick. Wish I still had the Master |Mobile BandSpanner.

I used base matching coils and capacitors, and a MFJ 914 autotuner extender with a small 100 WATT Kenwood mobile matchbox..
Different antennas required different matching for best far field strength.

When stopped I would attach a long wire onto the mount and throw a 1/4 wave wire up into
a tree or available support. I had quick disconnects and could switch antennas quickly and
several times switched between the 1/4 wave wire and a whip.
The 1/4 wave wire was usually 1 to 2 S units higher signal trength receive and transmit.
On rare occassions the wire allowed contacts when the whip would not.

The bugcatcher allowed day time contacts from Atlanta Georgia to Arizona, Texas areas
on 40 meters when the other antennas would not. I ran a TS 670 on 40 SSB at 10 watts
for these tests. Other bands I used a IC735.

I have not had the pleasure of using a screwdriver antenna for mobile
operation.
I would think they would be similar to the bugcatcher.

I don't think so, the top loading with a 3-4" coil with a capacitive hat and short whip makes the
bug catcher the most efficient loaded mobile antenna out there.
(with a small base matching coil)
The screwdrivers are simply base loaded with a long whip, (not real efficient) but being tuned to
the current operating frequency is a big plus.

Remember when it comes to mobile antennas, the uglier they look, the better they work.

Thanks. Yes I believe the bugcatcher is the greatest.
BTW, a little off topic but funny antenna story.
I was traveling on the interstate 75 south from Atlanta and I was signalled to pull
over by State Patrol. I was not speeding so I stopped to see what was happening.
He came to car, Honda Civic, and asked why I had so many antennas on the car.
I had 8 antennas, 2 HF, 3 VHF and 2UHF and AM/FM whip.

I Explained that I was Radio Amateur and used several radios on different freequencies.
Thus different antennas.
He said I had been coming thru his VHF radio as I passed where he was parked.
I keyed up my radios one at a time and sure enough over the loud speaker I heard my voice.
It was the 10 meter radio. I asked if I could see his set up to see if there was a long wire that
acted as an antenna. In the trunk was the radio with no case on it.
He said he had been in the shop for repair the previous day and it was fixed.
I told him to go back to the shop and get the case so the radio would be shielded.

He asked about how to become a ham and I demonstrated my radios on 20 and 15 meters
and the local 2 meter repeater. I gave him a flyer from the ARRL and Atlanta radio club and
told him they had classes to help people learn the rules and tech info needed to pass the test.
I had a TECH liscense study guide my son and wife had used to get their license with me. So I gave it to him

About 3 months later I was again on the same stretch of road when I heard my call on 2 meters, very loud.
Behind me was the trooper and he had a 2 meter rig in the car. He had just received his license.

I had not known it but he told me a good friend of his was a trooper in Florida out of Titusville.
Well it turned out that I was also good friends with TOM and he was also a HAM.
So you never know when or where you will become an ambassador for ham radio.

It pays to have something to give people when they ask.
I also later enjoyed several afternoons at the troopers house watching
Georgia Football on TV.

Related to this string, today, I constructed a ZS6BKW antenna, using 40 ft of 450 ladder line & abt 6 ft of RG-223 coax into the shack. SWR was less than 1.7:1 on all but 10M, 15M & 30M. 10M came in at 2.5:1, at 28.050. 40M had zero power reflected on 7.050. I could probably tweak the ladder line length, but it's not really worth the effort. They all tuned fine with the MFJ-962D.

Next step is to run the ladder line directly to the MFJ tuner.

This antenna is similar to the G5RV, but a little shorter, and with low SWR on several bands. It seems to be performing better than my ground mounted Hustler 4BTV by a couple of S-units. The apex is at 30 ft.

Here's a good link for the antenna:

http://www.nonstopsystems.com/radio/frank_radio_antenna_ZS6BKW.htm

From: aa2id@aol.com
Topic: 21802 Message: 21843

I really thought the original comments concerning code was very
interesting.
It wasn't until the argument, about its being said on this site
started, that I found I was using the delete Key.

I do appreciate all the info available on the list.

Merry Christmas and Happy New Year, everyone.

Hal AA2ID

PS: to make it legal, this is coming from my antenna, a horizontal
loop.

I delete freely and keep everything else forever.
I only leave a group when they start talking about car or boat engines.

21844. 2012 is fast approaching...

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-31 19:19:59 UTC
From: KE5LIB
Topic: 21844 Message: 21844

Hello folks...

I posted this to the Yahoo! GE MVS group, and found myself
hard put to think of anything better to say as far as New
Years goes... so I offer this to all here in the spirit and
hope that 2012 will be a much better year than the last three...

Ahem... mi mi mi... here goes... (sprays throat with something
from a weird looking bottle, and blows into a pitch pipe)...

2012 is fast approaching, and am I ever hoping it'll be much better than 2011, folks...

Here's my thank you to all of you for joining our group and
being a part of it all. And a prayer that God watch over all
of us, and our families as the time swiftly passes, and unfolds
anew before us all. There is still much to be thankful for, and
the association we have as hams is a remarkable thing. We are
among the rare few that reach outside the commonplace means of
contacting others, enjoying a remarkable camaraderie that defies
distance, space and time, and unites us all in a wonderful way!

May it be that...

We are never called upon to render our services for a true emergency,
but remain always vigilant and ready to do so. Better to be an armchair general than a
battle-weary private. But keep that go kit ready, just in case, and those batteries
charged!! And I didn't say anything about changes of underwear or deodorant! But do
remember this: "Blessed are the merciful, for they shall OBTAIN mercy". Be proactive and
pack well!!

We share with others this simple miracle of communication, unaffected
by things beyond control, like other means of communication have to face, and deal with.
And the best part? NO RATE PLAN INCREASES!!!

We appreciate every privilege, band, opportunity and chance to further
our advancement in our licensing and our hobby, guarding our precious
allocations of bandwidths by use and education, experimentation and advocacy, instead of
complaining about things. The parable about the "talents" and the men entrusted with their
care, investment and keeping applies here!

We continue to keep in perspective what we do as hams, never neglecting our duties and
responsibilities, and the most precious
relationships we have; namely our families and spouses. Radio is
a wonderful part of our life, and it can enhance many aspects of it
if we share our hobby with those we love. My YF Judy just loves the fact that I'm a ham!
She is proud to tell all her friends that she NEVER has to worry about keeping me out of
the bars and out of trouble!

When we think that there is nothing more the hobby of amateur radio can offer us, let us offer something for it- the best way to learn something is to teach what we know about it, and the best way to rekindle enthusiasm is to share what we know, and see the all-too-familiar excitement in their eyes that was once in ours, and like sparks from a fire, it'll "light us up" all over again! If ya
gotta "feel the burn", this is the best way!

If there is a moment when we can think we have been slighted, injured or mistreated, but we aren't sure, instead of allowing the bitterness to take hold, shake it off instead and keep going. Things are really sometimes not what they seem, and thank God for that!! This is one instance where it really is nice to be mistaken!!

We make it a point to learn something, no matter what "size" it is.
At least once a week. This is what keeps us fresh and new, and current. And yes it takes work, but think of the reward. You've staved off the monster of senility for another day!!

Finding humor comes easier and easier. Whoever said that laughter is a "cry of respiratory distress" must have been bored witless. There is so much humor around a person that nary a frown should take shape. And it's really easier to think of something funny than it is to think of anything else. Did I mention anything about endorphins?
Laughter is a helluva way to release them- better than running!!
And for some of us fat people that means fewer bruises and black eyes!!

As you count your blessings, remember just one thing- there are folk that are just as crazy as you are right here at Yahoo! GE MVS Group.
You are part of an elite society in more ways than you can shake a stick at, whatever that means...

So, Happy New Year, y'all, and 73!!

Mark KE5LIB

Well...

(That was Ronald Reagan's favorite speech opener...)

I endured the hilarity and blessed bowel obstructing ignorance of the politics and posturing in rabbit breeder forums, and all the ridiculous PETArded crap about the "animal rights terrorists". Personally, anyone with that much time on their hands to faunch and fume about perceived injuries and slights from their following, rather that the ones they ardently rail about, should be given a large volume ice water enema, buttered, roasted on a spit over an open flame, then thrown to the coyotes.

This is actually refreshing. I've learned so much about antennas here.
And yes. I had code down before it was no longer required, and all I can say to the whole "dumbing down" view?

If you wanna see me dumbed down, watch me slog bravely through Echolink!!

just me dos centavos, chums... 73!

21849. Loop Update + Happy New Year

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-31 21:50:34 UTC
From: goldtr8@charter.net
Topic: 21849 Message: 21849

Dear All

First let me say Happy New to everyone.

Second I have changed my balun from a 1:1 to a 4:1 and it seemed to wake the antenna up even more with radio.

There are some areas where it is now resonant without a tuner and this to me is amazing with a simple balun change.

Last night I heard Antartica as a legit S7 on the loop, too bad they did not hear me thru the pile up but they did not spend a lot of time on the 8 call land.

Again thank you to everyone who has provided me help in this project as it was most definately worth the effort.

Happy New Year to all and may you have great DX in 2012

21850. End fed length question?

Yahoo group: ham-antennas (2011-08 — 2011-12)
Date: 2011-12-31 23:59:53 UTC
From: Jim Whitaker
Topic: 21850 Message: 21850

I'm building an end fed with a 9:1 UNUN which I've already wound. Now my one and only question is, is there any reason to actually cut the radiator wire to 1/2 wave length at the lowest frequency as opposed to just throwing a slightly longer piece of wire I happen to have laying around(75 feet)? I'm building this as an emergency antenna.

DE N8XYN Jim K
